They will fight to the bitter end, and are doing great damage by means of half truths as well as by deliberate falsifications. It is exceedingly difficult to get rid of the harm caused by these tactics; hence, while not agreeing with every action or word of such energetic men as Mr. R. Hammond, it must be conceded that his activity has done much to interest local authorities in matters electrical. We take him as a keen man of business, preferring to carry on a crusade in the enemy's camp rather than to wait a request or to repel an attack. He may in many qualities fall far behind other members of the profession, but undoubtedly he has the tact and the ability to make men believe in the possibilities of electric lighting, and, after all, this ability is quite as valuable as ability in other directions. We must somehow or other reach the ears and eyes of purchasers, and drive home the fact that the opinion frequently expressed about the cost of the electric light is wrong. From interested parties we are continually informed that companies have not paid dividends, that capitalists have lost money, and that it cannot be otherwise, because the cost of electric energy precludes favourable competition with gas. In making sweeping statements of this kind great care is taken not to give the exact conditions existing whereby to make the comparison. Over and over again it has been proved that electricity can compete with gas, and we ought to get rid of such statements as appear in the report of the Hackney Local Board, to the effect that "it would appear that at present electric light costs double, or almost double, the price of gas." That statement is wrong, and is just about the same as it would be to compare the cost of gas where a £500,000 gas plant was supplying one thousand gas burners, as against a similar electric plant supplying five hundred thousand burners. Now, condition for condition, and the electric light will beat gas hollow. It can compete with it in price, and in every other desideratum it is far and away the more preferable. A number of accidents attributed to electric lighting are due to gas. Both electric light mains and gas mains leak—the leakage of the former will do no harm, unless perchance the leakage of the latter gives it an opportunity. If there happens to be an accumulation of gas in culvert or manhole the insulating air may be turned into an explosive mixture, and electricity may act upon it; but electricity is no more to blame than gas, and the fact should be driven home to the minds of the public. We find another text in the report above referred to, that electric light "if adopted in main streets, as is generally the case, would benefit those streets, while the burden of extra cost would partly fall on streets deriving no benefit." Surely it is not quite fair to isolate each street in this fashion. The trade of a whole neighbourhood is in its principal streets. These streets, again, are common property, used by every dweller in the side streets, and it is important for the welfare of the dwellers in side streets that they should have well-paved and well-lighted principal streets in which to carry on business and travel. The principal streets are usually better paved and better lighted than the side streets, and we never yet heard townspeople or residents murmur that this was unjust. If we take the Metropolis, who benefits by a well-lighted and paved Oxford-street? Not the residents in Oxford-street only, but everyone who comes to do business there, or who passes through the street to business or to his home. These and many similar questions can and should be discussed by those who are in a position to enlighten local authorities and the general public. The technical journals are fairly powerful with the former, but the constituents of the members of the various authorities they cannot reach.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

MOTOR GEARING FOR ELECTRIC TRAMCARS.

SIR,—Referring to your article on "Motor Gearing for Electric Tramcars" in your issue of November 10th, p. 441, your statements hardly give the credit due to leather link belting, and I have *not* abandoned it in favour of worm or any other gearing. For piers and level roads generally where it is clean ballast, and an edge rail can be used, I should continue to use it. There is an entire absence of noise, and any defects can be seen in time to be remedied; the motor can be entirely supported by the car framing, so that the springs carry the weight, and the rail hammering which occurs when motors are hung on the axles is entirely avoided. Of course, worm gearing is also noiseless.

But a very important matter is the question of power. With our two leather belt driven cars our 12 h.p. gas-engine can start both at once with the heaviest load of passengers owing to the slight slip of the belt allowing the motor to ease ahead a little when starting. With the worm wheel driven cars, one takes all the power of the engine to start it, although when fairly under weigh it takes no more current than the old belt-driven cars, so that for small, clean, level tracks this consideration is important.

I should not advocate belts for hilly and dirty routes. Flat solid belting is quite useless for the short drives and small pulleys obligatory in tramcars.

The quietness of belting is also an important matter, and must not be overlooked; and after 10 years of experience, any new cars I have for this road will be belt driven.

To show that the traffic dealt with is considerable, it may be mentioned that it equals 170,000 persons per car per annum, with a maximum of 3,250 persons per car per day (bank holiday), which with a 12-h.p. old type gas-engine is not bad.—Yours, etc., MAGNUS VOLK.

Volk's Electric Railway, Brighton.

[It will be seen that Mr. Volk's remarks, though very interesting, do not seriously contradict the statements made in the article above mentioned. The lines intended to be discussed therein were more especially those upon roads and streets, or public highways generally, and not so much the enclosed railways on piers or in places where other wheeled traffic is absent or unusual.—THE WRITER OF THE ARTICLE.]

ELIESON ACCUMULATOR (BRITISH PATENT) SYNDICATE, LIMITED v. THE EARL OF GALLOWAY.

SIR,—Will you allow me a small space in your issue to correct an impression which has been created that I am connected in some way with the plaintiffs in this case?

In July, 1892, I gave an option to acquire my patent for electric accumulators during a period only of 60 days and upon the terms that a company should be formed having a subscribed capital of £6,000. Mr. Watson Smith registered the plaintiff company for that purpose, but the stipulated capital was never subscribed, nor were any directors appointed, and my offer consequently lapsed so long ago as October 17, 1892.

On June 29, 1893, a new company was formed under

the title of the Lamina Accumulator (Elieson's British Patents) Syndicate, Limited, and the necessary capital subscribed. I have duly transferred my patent to the last-named company, of which the Earl of Galloway was and is still the chairman.

It is, therefore, the abortive company which brought the action against the Earl of Galloway in which judgment has been given in his favour.—Yours, etc.,

C. P. ELIESON.

Broad-street-avenue, November 22, 1893.

[The case referred to by Mr. Elieson was dealt with in our last issue, and the conclusion of it is reported in another column.—ED. *E. E.*]

OIL AS FUEL.

SIR,—In your notes, November 3rd, you have an article on "Oil as Fuel." I have found oil refuse answer very well, but cost is rather prohibitive, being about £4 per ton.

I have used common coal tar for upwards of 12 months, and have no coal on the premises. This can be burned without smoke at a cost of £1 per ton. I find two barrels (about 8s.) take the place of one ton of ordinary coal, 14s.—Yours, etc.,

SYDNEY CHEELD.

Waterside Ironworks, Chesham, Bucks., November 20th, 1893.

LOAD FACTORS OF ELECTRIC TRAMWAY PLANTS.

BY FRANK B. LEA.

The recent meeting of an American street railway convention was very notable for the absoluteness with which electrical topics held the field. For some time past, indeed, each annual assembly of this kind has witnessed a gradual dropping out of "horse" talk, and an increasing amount of discussion upon electric traction; and at present in America forage and fodder are almost without interest to the tramway man. Not the least important of the subjects dealt with at the meeting above noticed was the question of employing accumulators or storage batteries in the generating station for the purpose of evening-up the load, not only throughout the day, but also from one minute to another, and this question was very fully treated by Mr. C. O. Mailloux in a special report to the convention. It is not altogether the present writer's object to criticise this report, because it would have for English and American readers two very different values; some slight comment, however, is necessary in order to define the base upon which future investigations into this subject may be founded.

It should be remembered, in the first place, that storage batteries have, for central station work, obtained no position whatever of importance in the United States, whilst on this side the Atlantic they enter into the design of almost all continuous-current supply stations. Therefore, the greater part of Mr. Mailloux's report is taken up with details gathered from various sources concerning the reliability and powers in general of accumulators as an adjunct to central-station work—whether for light or power distribution being, for that matter, of no consequence. In England and on the Continent such a question has gone past the "is it possible" stage: we take it as an axiom that accumulators serve a useful purpose. Whether it be an economical one is another matter, to be discussed later on.

In the first section of his report, however, Mr. Mailloux—in sketching out the characteristics and requirements of an electric tramway generating station—gives an interesting summary or statement of the position, from which may be, I think, seen at once just how far the employment of accumulators to help the generating plant is at all justifiable or worthy of consideration. It must not, however, be forgotten that there are more ways of killing a cat than by choking it with butter, and there are conceivable sources of reserve power (other than storage batteries) from which occasional drafts may be taken for an overload on the generating plant. It is with a view to elucidating some details of such, and comparing them together, that this article is written.

Mr. Mailloux gives in his report some very interesting figures and diagrams to show the enormous variations that take place in the output of an electric tramway generating station; and differentiates in an excellent way between what he calls the "fluctuations," or momentary changes in the total power demanded on the line (due to cars starting or stopping, running up and down hill, etc.), and the "variations," or changes occurring at several periods during the day when the traffic upon the line is exceptionally heavy (due to more cars being run, or more passengers carried, or both combined).

These variations or changes are, of course, well known to every electrical engineer who takes an interest in traction work, and have received much attention in consequence. I do not, however, think that Mr. Mailloux has been very successful or happy in the choice of terms to express these changes in output, for "variations" and "fluctuations" have to all intents and purposes the same meaning to the average man. Since he himself speaks of these changes as "waves," I would suggest that this expression be kept solely for the fluctuations or momentary changes. The idea of the changes that occur at tolerably fixed periods in the day will then be very clearly conveyed by speaking of them as "tides."

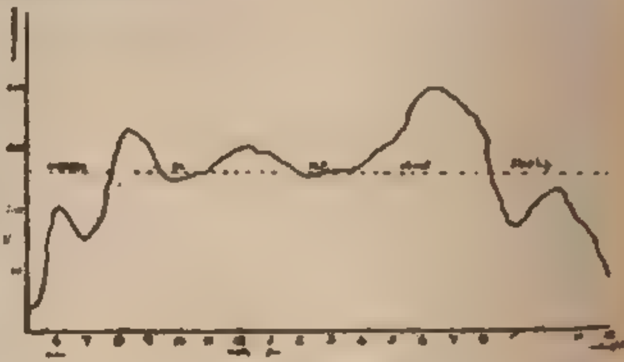

FIG. 1.—"Tides."

To show this contrast more clearly, the annexed diagrams may be of service. Fig. 1 represents a curve of "tides"—of course approximate only, and (it may be) exaggerated throughout. The total output spread over the working day is here shown in diagrammatic form, say, on a double line eight miles long, fairly level, with a total of 20 to 30 cars in operation. The "peaks," or points of maximum output, are, it will be seen, five in number, corresponding with the early morning cars for workmen; the eight o'clock service for clerks and business men; a similar one, but larger, at noon or one o'clock; the heaviest demand of all about 6 p.m., when work ceases for the day with the majority; and a final call after 10.30 p.m., when the theatres and places of amusement are closed.

FIG. 2.—"Waves."

Of course hardly any two lines will have similar load curves: the route followed, the districts served, and the class of passengers, will each and all exercise an important influence upon the total output of a generating station; but as a typical instance, the curve now given will serve to show the ups and downs of a very favourably situated line.

Taking the average output at 260 h.p., with a maximum of, say, 400 h.p., it will be seen that almost throughout the day a load factor is secured that would make an electric light station engineer green with envy. The greatest variations, indeed, are not more than from, say, half the mean load to less than double thereof, or from 50 per cent. below to 70 per cent. above.

The second diagram, Fig. 2, is a reproduction of a load

curve given by Mr. J. Greathead during a discussion upon Dr. Hopkinson's paper, entitled "Electrical Railways," read some months ago before the Institution of Civil Engineers. This curve is intended to illustrate the extent of "waves" in the output of an electric tramway station, as compared with the "tides" just mentioned. It is drawn up from instrument readings upon the City and South London Railway, with seven trains in operation upon the line, running on a headway of five minutes.

In less than five minutes, it will be seen the load curve crosses or touches the line of average horse power ten times, and varies from the 100-h.p. to the 300-h.p. mark within two minutes. Our electric light station engineer—who was green with envy a short time ago—will now feel a flush of satisfaction that his output does not vary quite so enormously as this, but comes on and off in pretty steady fashion, rising and falling by tens rather than hundreds of horse-power. Although, therefore, the tramway generating station has the advantage of four or five peaks in the day's load curve, as compared with only one, or perhaps two, in that of an electric lighting station, yet the "waves," or momentary fluctuations in the latter, are of little importance in comparison with those engendered by the constant stopping and starting of cars upon the tramway, or by their running in combination up or down grades at any instant.

The prime movers in a tramway station may be worked all day long at an average load of perhaps 60 per cent., but they must be excellently well governed, or must have very heavy flywheels, in order to prevent racing or a sudden pull-up when the load varies from zero to the maximum in the course of a minute or two.

It is worth remembering, moreover, that the instance given of "waves" does not represent by any means the type of greatest variation: the City and South London Railway is a line having fixed stopping places, with the stations placed on the top of inclines each way (so that power may be saved at such points), and with trains keeping a regular schedule. On an ordinary street tramway, the stops are, as a rule, quite arbitrary, the grades must be taken as they come—perhaps altogether in one section of the line—and the state of general traffic may render it difficult to prevent cars from bunching, two or three following one another in close order.

(To be continued.)

FITZGERALD'S IMPROVED LITHANODE AND SPONGY-LEAD PLATES.

Every voltaic battery—primary or secondary—is made up of a positive and a negative element immersed in an electrolyte or "exciting fluid." The positive element is usually zinc; but spongy lead, though it does not generate so high an electromotive force, is more convenient for long-continued use. For many years the impression prevailed that the positive element—the one consumed or oxidised when the battery is worked—was practically of greater importance than the negative. The contrary is now recognised as being the fact; the main point is to obtain a negative element that will not "polarise"—that is, become coated with hydrogen by electro-deposition. To obviate the effect of polarisation, the negative plate, if of carbon or platinum, is immersed in a powerful oxidant, such as nitric or chromic acid, or is surrounded by a solid oxidant such as binoxide of manganese. There is one plate, and one only, that does not require to be associated with an oxidant, since it is in itself (being almost wholly composed of peroxide of lead in a highly conductive form) the most powerful solid oxidant known, parting with its oxygen (to oxidise hydrogen) when "discharged," and absorbing it again when "charged," without ever becoming consumed or deteriorated when properly used. This negative element *par excellence* is *lithanode*.

Speaking of this material, a most trustworthy authority, Mr. J. T. Sprague, says: "Lithanode is a solid form of lead peroxide, and is the most practically useful form of the material." "Lithanode makes an excellent plate in secondary batteries, and is more especially adapted for small portable cells, where it is close upon perfection. It would be so for large cells also if the connection to it could be made of lower resistance." (This desideratum, it may be stated, has now been obtained.)

Mr. W. H. Preece, F.R.S., electrician to the Post Office, says: "I have had a cell (FitzGerald's lithanode) which gave a return as high as 5·7 ampere-hours per pound." (That is, per pound of *cell* complete.)

A well known medical man, writing to the *English Mechanic*, and of a correspondent of that journal, said: "I will show him lithanode cells that have been working a lamp intermittently for 18 months, and may also be able to give him some information about this (to me) invaluable product.—CHIRURGO, 7, Mornington-crescent, Hampstead-road."

With zinc and dilute sulphuric acid of sp. g. 1,160, lithanode gives an electromotive force of 2½ volts; so exactly, when the lithanode is in its normal condition, that the couple is sometimes used as a practical standard of electromotive force. With spongy lead and acid of sp. g. 1,182, lithanode gives two volts, which may be taken as the average E.M.F. of a lead secondary battery. Acid of this sp. g. contains 25 per cent. by weight of strong oil of vitriol (H_2SO_4).

The minimum capacity of fully-charged lithanode is one ampere-hour per ounce avoirdupois. That is to say, a ½lb. plate should yield a current of, say, half an ampere for 16 hours before its electromotive force (with spongy lead) falls from 2 to 1·8 volts. Lithanode (and other peroxide elements) should never be discharged beyond this point; indeed, it is better that the E.M.F. should not fall below 1·75 volts. The additional quantity that can be utilised by urging the discharge beyond this point is comparatively small; the current being no longer steady, and, when 1·8 volts has been reached, the fall of E.M.F. is rapid.

Practically, the capacity of spongy lead is taken as twice that of the lithanode plate. Theoretically, its capacity is much greater; but a large proportion of metallic lead must be left unconverted with sulphate in order to allow of the plate being recharged. The weight of the spongy-lead element need not, however, be more than half that of the lithanode plate.

The zinc-lithanode couple is most conveniently used as a primary battery—that is to say, when the couple is run down and the E.M.F. has commenced to fall rapidly, the electrolyte is thrown away and replaced by fresh dilute sulphuric acid of sp. g. not over 1,200, the zinc is reamalgamated, and a fresh lithanode plate is substituted for the old one, which may be put aside to be recharged when a sufficient weight of old plates has been collected to render it worth while to return them to the works. Lithanode is not affected by being left for a lengthened period in the acid; but zinc is, even when carefully amalgamated. Another objection to the use of the zinc-lithanode couple as a secondary battery is that you cannot practically recover all your zinc by recharging, so that sulphate of zinc accumulates in the electrolyte, and, by crystallising, gives rise to "creeping" and efflorescence. The lead-lithanode couple is entirely free from this inconvenience, and the spongy-lead element, as well as the lithanode, regains its original capacity.

The capacity for a given extent of surface of course varies with the thickness. Lithanode plates $\frac{3}{16}$in. thick have a capacity of about 40 ampere-hours per square foot of surface (taken on both sides of the plate); that is, about ·28 ampere-hour per square inch.

The improved lithanode plates most commonly made are ½lb. plates having about the following dimensions: 4¾in. by 3in. by $\frac{3}{16}$in. They can easily be cut by means of a fret or circular saw to any required smaller size, and sizes larger than the above can be obtained. The material is also readily drilled.

One of the most important points in connection with lithanode is the mode of making contact with it. One method, the only objection to which is that for many purposes it is too expensive, more especially for a *low-resistance* contact, is to apply to the surface of the material, by means of an ebonised screw and nut, a perforated disc of platinum foil, having a wire of the same metal in contact with it; a steady pressure being obtained by means of a

washer of caoutchouc. Plates with embedded contact strips of gilded lead, or gilded lead strips, to be clamped to the plate as above described, are now used.

When lithanode plates are mounted with an oxidisable metal, such as ordinary lead, one of the greatest advantages of the material is sacrificed—viz., the ability to retain its charge for any length of time when immersed in the electrolyte. The contact with an oxidisable metal reproduces, in fact, the great defect of all other lead accumulators, setting up a local action by which the active material and the support or contact mutually destroy each other.

ON THE EVOLUTION OF GAS DURING THE CHARGING OF ACCUMULATORS.*

BY C. BRUEGEMANN.

The author gives the results of about 20 experiments, in which the conditions governing the evolution of gas during the charging of accumulators were investigated. The cells used consisted of a positive plate, 8·5 centimetres long by 7·5 centimetres wide, suspended between two similar negative plates, at a distance of eight millimetres from it. The positive plate was coated on both sides with the active material, but the negative plates were coated only on the inner sides, so that the efficient area of both cathode and anode was practically the same—viz., 127 5 square centimetres. They were contained in glass vessels about half a litre capacity.

In order to collect the gases, each cell was closed with a cover of solid paraffin, through which passed two glass tubes. One, dipping into the acid served for filling the cell, and enabled the density of the liquid to be measured from time to time; the other opening into a funnel shaped cover, afforded a means of collecting the gas. The strength and E.M.F. of the current were measured by two Siemens torsion galvanometers, and at the commencement of an experiment the cell was completely filled with liquid. At suitable intervals samples of the gas were collected for analysis. Two characteristic experiments are given in detail. Cell No. 1 was in good working order, but in No. 2 there was local action.

—	Charge.				Total gas evolved in cubic centimetres.	Discharge.			
	Current strength in amperes.	Mean E.M.F. in volts.	Ampere hours.	Watt-hours.		Current strength in amperes.	Mean E.M.F. in volts.	Ampere hours.	Watt-hours.
No. 1	0 5	2·20	3·75	8·25	216·0	0·5	1·89	3 67	6·92
2	0 5	2·25	5 50	12 38	1,272 0	0 5	1 95	3·25	6·34

The experiment was made under the most favourable conditions for No. 2, the discharge being commenced directly the charging was completed, and yet the efficiency in ampere-hours was 38 8 per cent. less than that of No. 1, and in watt-hours 32·7 per cent. less.

The E.M.F. of No. 1 remained almost constant during the first two-thirds of the charging. It then rose, gradually at first, and afterwards rapidly, to a maximum of 2 71 volts But in the case of No. 2, in which there was local action, the E.M.F. rose steadily from the first, the rate only slightly increasing at about the same period of the charging when the rapid rise took place in No. 1. But the maximum attained in 20 hours was only 2 4 volts. There was a marked difference in the rate at which gas was given off, and also in its composition. With No. 1 oxygen appeared first 5½ hours after the current was turned on, and 40 minutes later hydrogen began to be evolved in rapidly-increasing quantity, the proportion 2 to 1 being reached after about an hour, at which time the E.M.F. was nearly at a maximum.

With No. 2, hydrogen was given off to a considerable extent from the very first, the oxygen only appearing after four hours and 40 minutes. At about the eighth hour oxygen was being evolved in the proportion of 14 to 16 of hydrogen. After this it decreased in amount, and at the eleventh hour the proportions were nearly normal. The author considers that the charging should be stopped when the E.M.F. begins to rise rapidly, in order to avoid the loss of energy, corresponding to the evolution of gas which then takes place. Within certain limits the strength of the charging current does not appear to affect the results. The same total volume of gas, having the same average composition, was given off when currents varying from 0·3 to 0·8 ampere were employed. Experiments were made as to the waste of energy from local action in a charged accumulator. During the first four hours seven cubic centimetres of hydrogen were given off per hour, but by the eighth day the amount had fallen to 1·3 cubic centimetre. It would appear, therefore, that the rate of loss is not constant, as had been supposed. The author points out the great importance of using pure acid and perfectly clean water for filling the cells.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE V.

(Continued from page 467.)

If the air is compressed isothermally, as it very nearly is in modern compound compressors, then the question arises, how much work is obtained in the compressed-air motor? If the air is used non expansively, as in the smaller motors used in Paris, and in much compressed-air plant, used for rock drilling and similar purposes, the work done in the motor is simply the admission work, $P_1 V_1$, less the work of expulsion, $P_a V_1$, neglecting valve resistance and friction—that is, the work obtained is—

$$P_a V_a \left(1 - \frac{P_a}{P_1}\right).$$

The efficiency of combined motor and compressor is then—

$$\eta = \frac{1 - \frac{P_a}{P_1}}{\log_e \frac{P_1}{P_a}}$$

$P_1 =$	2	3	4	6	8	10 atmospheres
$\eta =$	0 72	0·61	0·54	0·46	0·42	0·39.

The efficiency diminishes rapidly with increase of initial pressure, and it is the use of bad and inefficient air plants of this kind which has given compressed air a bad name and made engineers hesitate to adopt high working pressures. To obtain good results, the air must be used expansively. Suppose the air expands in the motor without gain or loss of heat, a realisable condition, and let clearance and loss in mains be neglected, as well as friction, then the indicator diagram of the motor will be A B F M, the expansion curve being an adiabatic, F M, and the air cooling during expansion. The efficiency of the whole arrangement will be the ratio of the area A B F M to the area A B F D. It is easy to show that that efficiency is given by the equation—

$$\eta = \frac{95{,}600 \left[1 - \left(\frac{P_a}{P_1}\right)^{0·29}\right]}{27{,}710 \; \log_e \frac{P_1}{P_a}}$$

RESULTANT EFFICIENCY OF COMPRESSOR AND MOTOR.

Working pressure pounds per square inch. By gauge.	Absolute P_1	$\frac{P_1}{P_a}$	η
14·7	29·4	2	·906
44·1	58 8	4	·824
73·5	88·2	6	·780
102 9	117·6	8	·752

Practically, it is necessary to use pressures of 45lb per square inch at least, that the apparatus may not be too cumbrous. The calculation shows that when using the air properly, much higher working pressures may be adopted without sensible loss of efficiency.

Various means have been adopted to cool the air during compression. Sommeiller adopted water pistons, which are very effective, and in the early compressors at Mont Cenis very good results were obtained But there are practical objections to water-piston compressors; they must be worked slowly, and are costly and cumbrous. In the St. Gothard compressors the much less

* Howard Lectures delivered before the Society of Arts

effective arrangement of a cold-water jacket was adopted; but air does not part with heat readily to a metal cylinder, and the cooling surface of the cylinder is too small to permit much of the heat to be abstracted; hence, later, a method proposed by Prof. Colladon of injecting a water spray into the cylinder was adopted, and by this means a much more cooling action was obtained. To some extent, however, the cooling action of the spray is deceptive: the cooling takes place partly in the passages of discharge, and the compression curve is not lowered so much as it should be.

Compound Compressors.—The author is not aware when compound compressors were first used. They were, it is believed,

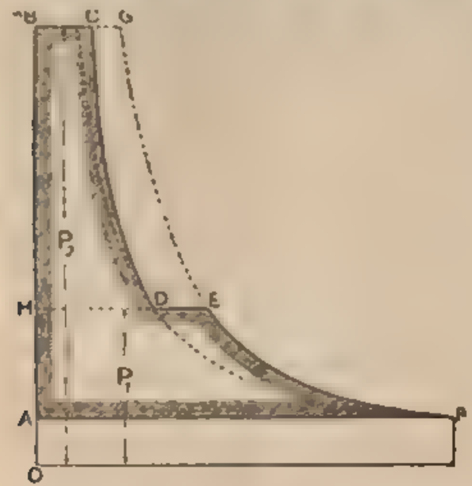

FIG. 25.

used by Mekarski, and, possibly, by others, in cases where a high pressure was required, at a comparatively early date. Mr. Northcott made a two stage compressor, with intermediate cooling arrangements in 1878. The Norwalk Company, in America, constructed compound compressors for mines in 1880, apparently more with a view to equalise the effort during the stroke than to obtain higher efficiency. In 1881, however, they introduced an inter-cooler between the high and low pressure compression cylinders. This consisted of a reservoir with thin brass pipes through which cold water circulated. The effect of this intermediate cooling is very important in reducing the heating loss. The compound diagram is shown in Fig. 25. Air is compressed to P_1 in the low pressure cylinder. Then, in passing through the inter-cooler, it shrinks in volume from H E to H D. It is then further compressed to P_2 in the high pressure cylinder. The work saved by the intermediate cooling is the area E D C G. The adoption of these compound compressors is important, because it removes the chief objection to the use of high working pressures in a system of compressed air transmission.

Compressor Valves.—In most compressors simple fluid-moved valves are employed. The objection to them is that they create some prejudicial resistance involving waste of work, and they prevent the compressor being worked at high speed. In many compressors mechanically moved valves are employed, for instance slide or Corliss valves. The compressor can then be run faster, but the resistance at the valves is still serious. Prof. Riedler uses valves which open automatically and are closed mechanically, and these no doubt obviate the objections to ordinary valves. Fig. 26 shows one form. This is a flap valve so set that it tends to open. It is closed by a lever worked by a cam.

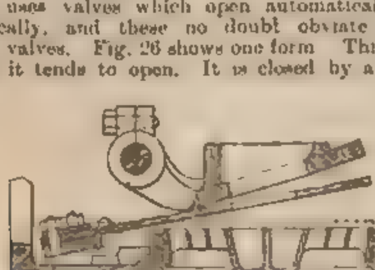

FIG. 26.

Mr. Pearsall's Hydraulic Air-Compressing Engine.—Mr. H. D. Pearsall, apparently incited by a study of the early hydraulic ram compressors of Sommeiller, has designed a very interesting hydraulic compressing engine, in which air is compressed directly by a water column, without cylinders and pistons.

Fig. 27 shows this engine in section. A is the supply-pipe, by which water, with the energy due to its descent from a higher level, flows into the apparatus. C is a large cylinder valve which, when open, allows the water to flow out into the tail-race, and, when shut, forces the column of water to rise into the compression chamber, M. The column of water in the supply pipe is allowed to acquire velocity by outflow into the tail race. The valve, C, is then mechanically closed, and the descending column expends its energy in compressing the air in the chamber, M, and discharging it into the receiver, E. The cylinder valve, C, is actuated by a small air motor. The chamber, M, empties the water through the cylinder valve, C, and fills with air through the air valve, H, which is controlled by a float. The adjustment is such that the column of water can be made to come to rest at the instant when it reaches the delivery plate.

Mr. Pearsall claims that very high velocities of flow can be permitted without danger or loss of efficiency. Some experiments made with a small apparatus gave an efficiency of 80 per cent.

The engine is simple, and there seems no reason why it should not have a high efficiency. But till experiments have been made on a larger scale, it is impossible to say what the delivering capacity of the machine in a given time is. Till that is determined it is uncertain whether it would be more costly or less costly than ordinary compressors worked by turbines.

Losses in Transmission.—The frictional resistances in a pipe conveying fluid are proportional to the density of the fluid; consequently, at equal velocities the frictional resistance of air is enormously less than that of water. Conversely, air may be transmitted in air mains without serious fall of pressure, at 10 or 20 times the velocity practicable with water in water-mains. Air, at 90lb. per square inch pressure, is about 115 times lighter than water, and the frictional resistance, at equal velocities, is less than 1 per cent. of that of water. In air mains there is nothing analogous to the hydraulic shock, due to changes of velocity, which, as well as the friction, leads to a limitation of the velocity of water in mains to 3ft. per second, in most cases, or to 6ft. per second in some cases.

In air mains, velocities of 30ft. to 50ft. per second are allowed, without serious frictional loss. In consequence of this high velocity, large amounts of power can be transmitted by air at moderate pressures, and in mains of moderate dimensions.

The hydraulic mains of the London Hydraulic Power Company are 6in. in diameter, the pressure is 750lb. per square inch, and the velocity 3ft. per second. That corresponds to the transmission of 90 effective horse-power by each main. But air at 45lb. pressure per square inch, with a velocity of 50ft. per second, would transmit 150 effective horse-power in a main of the same size. The largest high pressure hydraulic mains are 7in. in diameter. But there is hardly any limit to the size of air mains. The new Paris main from the Quai de la Gare to the Place de la Concorde—seven kilometres in length—with air at 90lb. pressure per square inch, transmits 6,000 h.p.

In the older Paris mains which were carried through the sewers, and which had an exceptionally large number of bends, draining-boxes, and other sources of resistance, the frictional resistance, with a velocity of 25ft. to 30ft. per second, only amounted to 2lb. per square inch per mile of main. It would be only in very long distance transmissions that the fall of pressure in the mains would be large enough to sensibly affect the efficiency of the system.

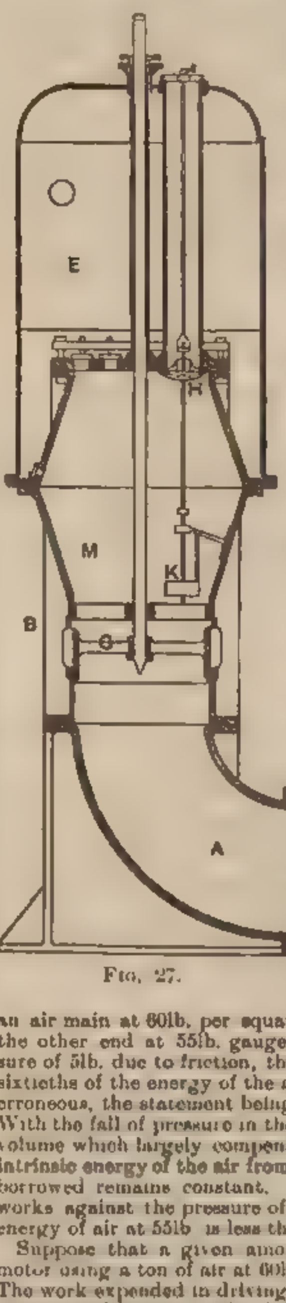

FIG. 27.

As to the precise way in which a fall of pressure in the mains influences the efficiency, there is a word to be said. If air enters an air main at 60lb. per square inch gauge pressure, and reaches the other end at 55lb. gauge pressure, there being a fall of pressure of 5lb. due to friction, then it is commonly stated that five-sixtieths of the energy of the air is wasted. But this is altogether erroneous, the statement being based on a false hydraulic analogy. With the fall of pressure in the case of air, there is an expansion of volume which largely compensates for the loss of pressure. The intrinsic energy of the air from which the work of the air motor is borrowed remains constant. It is only because the air motor works against the pressure of the atmosphere that the available energy of air at 55lb. is less than that of air at 60lb. pressure.

Suppose that a given amount of work can be done by an air motor using a ton of air at 60lb. gauge pressure, or 75lb. absolute. The work expended in driving this motor by a compressor adjacent to it would be the work of compressing one ton of air to 75lb. absolute pressure. Now let the compressor be removed to a couple of miles distance, and the air supplied to the motor through a main in which there is a fall of pressure of 5lb. per square inch. To do the same work as before, all that is necessary is that a ton of air should be compressed to 80lb. absolute pressure. The difference between the work of compressing a ton of air to 80lb. and to 75lb. absolute pressure is the loss of work arising out of the friction of the main, and this amounts with fairly good compressors to about 3 per cent.

In short distance transmissions the loss of pressure in the mains is so insignificant that it may be neglected. In long distance transmissions an accurate estimate of the frictional loss is necessary. The author believes that he has shown, using data derived from careful experiments on 20 miles of main in Paris, that long distance transmission of power by compressed air is perfectly practicable. It is possible, with compressors driven by engines working to

10,000 i.h.p. to transmit the air, in a main of not unusual size, a distance of 20 miles, and to obtain in motors worked by the transmitted compressed air from 4,000 i.h.p. to 5,000 i.h.p. if the air is used cold, or 6,000 i.h.p. to 7,000 i.h.p. if the air is reheated before use.

The Air Motors.—The air motor is essentially a reversed compressor, but it is free from the heating difficulty. The air cools in expanding, and, in some cases, this causes trouble from the production of ice in the valve passages. The rounding of the edges of the ports so that the ice can be pushed away diminishes the trouble, and heating the air before use entirely obviates it.

Some special rotary motors of small size are used in Paris, but they are not economical, and most of the motors are simply non-condensing steam engines adapted to use air. Probably the greatest cause of loss in air motors has been leakage, especially piston leakage. In a steam engine the condensation on the cylinder wall helps to make the piston tight. In an air motor the cylinder surface is dry, except so far as lubricant is supplied.

Cost of Working with Compressed Air.—Air motors can be obtained, erected complete, for two thirds of the cost of a steam engine and boiler. In the very imperfect small rotary motors in Paris, the consumption of air compressed to five atmospheres (75lb. per square inch) is 750 to 850 cubic feet per effective horse power hour. Old steam engines converted to air motors use 450 cubic feet per effective horse power hour. Now, the new compound air compressors at Paris compress a cubic metre of air to a higher pressure than this for 0.4 centime. If 0.75 centime per cubic metre is allowed to cover interest on plant, as well as cost of compression, this corresponds to 1d. per 880 cubic feet of compressed air. Hence the cost of working with compressed air amounts to 1d. per effective horse power hour with inefficient rotary motors, and about ½d. per effective horse power hour with the converted steam engines. In the latter case the cost corresponds to about £6. 5s. per effective horse power for a year of 3,000 working hours. Better results than these will be obtained when air motors are studied as carefully as air compressors.

(To be continued.)

BOARD OF TRADE AND TRACTION.

Draft Regulations made by the Board of Trade under the provisions of the —— Tramways Act, for regulating the employment of insulated returns, or of uninsulated metallic returns of low resistance; for preventing fusion or injurious electrolytic action of or on gas or water pipes or other metallic pipes, structures or substances; and for minimising as far as is reasonably practicable injurious interference with the electric wires, lines, and apparatus of parties other than the company, and the currents therein, whether such lines do or do not use the earth as a return.

Definitions.—In the following regulations:

The expression "energy" means electrical energy.

The expression "generator" means the dynamo or dynamos or other electrical apparatus used for the generation of energy.

The expression "motor" means any electric motor carried on a car and used for the conversion of energy.

The expression "pipe" means any gas or water pipe or other metallic pipe or structure or substance.

The expression "wire" means any wire or apparatus used for telegraphic, telephonic, electrical signalling, or other similar purposes.

The expression "current" means an electric current exceeding one thousandth part of one ampere.

The expression "the company" has the same meaning as in the Tramways Act.

Regulations.

1. Any dynamo used as a generator shall be of such pattern and construction as to be capable of producing a steady continuous current.*

2. One of the two conductors used for transmitting energy from the generator to the motors shall be in every case insulated throughout its length, and is hereinafter referred to as the "line"; the other may be insulated throughout, or may be uninsulated in such parts and to such extent as is provided in the following regulations, and is hereinafter referred to as the "return."

3. Where any rails on which cars run or any conductors laid between such rails form any part of a return, such part may be uninsulated. All other returns or parts of a return shall be insulated.

4. When any uninsulated conductor laid between the rails forms any part of a return, it shall be electrically connected to the rails at distances apart not exceeding 100ft. by means of copper strips having a sectional area of at least one-sixteenth of a square inch, or by other means of equal conductivity.

5. When any part of a return is uninsulated it shall be connected with the negative terminal of the generator, and in such case the negative terminal of the generator shall also be directly connected, through the current indicator hereinafter mentioned, to two separate earth connections which shall be placed not less than 20 yards apart. Provided that in place of such two earth connections the company may make one connection to a main for water supply of not less than 4in. internal diameter, with the consent of the owner thereof. Such earth connections shall be constructed, laid, and maintained, so as to secure contact with the general mass of earth, and so that an E.M.F. not exceeding four volts shall suffice to produce a current of at least two amperes from one earth connection to the other through the earth, and a test shall be made at least once in every month to ascertain whether this requirement is complied with. Where any portion of either earth connection is placed within 6ft. of any pipe, and the company are unable to obtain permission to metallically connect it with the earth connection, they shall provide, by means of non-conducting screen, that no current can pass between the pipe and the earth connection without traversing at least 6ft. of earth.

6. When the return is partly or entirely uninsulated, the company shall in the construction and maintenance of the tramway (a) separate the uninsulated return from the general mass of earth, and from any pipe in the vicinity; (b) connect together the several lengths of the rails; (c) adopt means for reducing the difference produced by the current between the potential of the uninsulated return at any one point and the potential of the uninsulated return at any other point; and (d) maintain the efficiency of the earth connections specified in the preceding regulations, so as to fulfil the following conditions, viz.: (i.) That the current passing from the earth connections to the generator shall not at any time exceed 10 amperes. (ii.) That if at any time and at any place a test be made by connecting a galvanometer or other current indicator to the uninsulated return and to any pipe in the vicinity, the direction of the current, if any, shall be from the return to the pipe and not *vice versâ*. (iii.) That under the conditions specified in (ii.) it shall always be possible to reverse the direction of the current by interposing a battery of three Leclanché cells connected in series.

In order to provide a continuous indication that the condition (i.) is complied with, the company shall place in a conspicuous position a suitable, properly connected, and correctly marked current indicator, and shall keep it connected during the whole time that the line is charged. The owner of any pipe may require the company to permit him to ascertain by test that the conditions (ii.) and (iii.) are complied with as regards his pipe.

7. When the return is partly or entirely uninsulated its electrical resistance shall be tested by the company at least once in every three months. If at any such testing it appears that the resistance has increased by more than 15 per cent. above the value recorded at the time the tramway was opened, the company shall take immediate steps to reduce the resistance to the said recorded value.

8. Every electrical connection with any pipe shall be so arranged as to admit of easy inspection, and shall be tested by the company at least once in every three months.

9. Every line and every insulated return or part of a return shall be constructed in sections not exceeding one half of a mile in length, and means shall be provided for isolating each such section for purposes of testing.

10. The insulation of the line and of the return when insulated, and of all feeders and other conductors shall be so maintained that the leakage current shall not exceed one hundredth of an ampere per mile of tramway. The leakage current shall be ascertained daily before or after the hours of running when the line is fully charged. If at any time it should be found that the leakage current exceeds one tenth of an ampere per mile of tramway, the running of the cars shall be stopped until the leak has been localised and removed.

11. The insulation resistance of all lines, insulated returns, feeders, or other conductors, laid below the surface of the ground, shall not be permitted to fall below the equivalent of 10 meghoms for a length of one mile. A test of the insulation resistance of each part of the circuit shall be made at least once in each month.

12. Where in any case in any part of the tramway the line is erected overhead and the return is laid on or under the ground, and where any wires have been erected or laid before the construction of the tramway in the same or nearly the same direction as such part of the tramway, the company shall if required so to do by the owners of such wires or any of them, permit such owners to insert and maintain in the company's line one or more induction coils or other apparatus for the purpose of preventing disturbance by electric induction.

13. Any insulated return shall be placed parallel to and at a distance not exceeding 3ft. from the line when the line and return are both erected overhead, or 18in. when they are both laid underground.

14. In the disposition, connections, and working of feeders the company shall avoid injurious interference with any existing wires.

15. The company shall so construct and maintain their system as to secure good contact been the motors and the line and return respectively, and they shall not allow sparking to occur at the rubbing or rolling contacts in any part.

16. In working the cars the current shall be varied as required by means of a rheostat containing at least 20 sections, or by some other equally efficient method of gradually varying resistance.

17. In the construction and use of their generator and motors the company shall take all reasonable precautions to prevent the occurrence of undue sparking.

18. Where the line or return or both are laid in a conduit, the following conditions shall be complied with in the construction and maintenance of such conduit: (a) The conduit shall be so constructed as to admit of easy inspection of, and access to, the conductors contained therein and of all insulators and supports. (b) It shall be so constructed as to be readily cleared of accumulation of dust or other *debris*, and no such accumulation shall be permitted to remain. (c) It shall be laid to such falls and so connected to sumps or other means of drainage as to automatically

* The Board of Trade will be prepared to consider the issue of regulations for the use of alternating currents for electrical traction on application.

clear itself of water without danger of the water at any time reaching the level of the conductors. (*d*) If the conduit is formed of metal, all separate lengths shall be so jointed as to secure metallic continuity for the passage of electric currents, and where the rails are used to form any part of the return they shall be electrically connected to the conduit by means of copper strips having a sectional area of at least one-sixteenth of a square inch, or other means of equal conductivity, at distances apart not exceeding 100ft. Where the return is wholly insulated and contained within the conduit, the latter shall be connected to earth at the generating station through a high-resistance galvanometer suitable for the indication of any contact or partial contact of either the line or the return with the conduit. (*e*) If the conduit is formed of any non-metallic material not being of high insulating quality and impervious to moisture throughout, and is placed within 6ft. of any pipe, a non-conducting screen shall be interposed between the conduit and the pipe, of such material and dimensions as shall provide that no current can pass between them without traversing at least 6ft. of earth.

19. The company shall, so far as may be applicable to their system of working, keep records as specified below. These records shall, if and when required, be forwarded for the information of the Board of Trade.

Daily Records.—Number of cars running. Maximum working current. Maximum working pressure. Maximum current from the earth connections (*vide* Regulation 6 (i.)). Leakage current (*vide* Regulation 10).

Monthly Records. — Condition of earth connections (*vide* Regulation 5). Insulation resistance of different conductors (*vide* Regulation 11).

Quarterly Records.—Resistance of return (*vide* Regulation 7). Conductance of joints to pipes (*vide* Regulation 8).

Occasional Records.—Any tests made under provisions of Regulation 6 (ii. and iii.); localisation and removal of leakage, stating time occupied; particulars of any abnormal occurrence affecting the electric working of the tramway.

LOCOMOTION IN LONDON.

The following is a copy of a draft report prepared by Mr. W. Saunders for consideration by the Public Health and Housing Committee of the London County Council:

In accordance with the resolution of the Council of October 3, we have considered "the best means of obtaining information on the question of locomotion in London, including railways, tramways, omnibuses, and steamboats." We recognise that the subject is one of supreme importance from sanitary, social, and commercial standpoints. The population and area of the Metropolis being far beyond that of any other city, the distances to be covered are so great that travelling facilities have become a necessity for all classes. The large increase of value which has taken place in business premises makes it essential to provide house accommodation on cheaper land than is available in business localities. Moreover, from the great extension of industrial establishments, it has become physically impossible to provide house accommodation in the neighbourhood of their employment for such multitudes as are now engaged in the industries of London.

From a sanitary point of view the question is equally pressing. There is no known method by which population can be crowded as in London without danger to health and loss of life. Additional air space is essential which can only be given by extending the area of occupation. This is impossible within the business limits of the Metropolis; room must be sought outside those limits and improved means of locomotion provided. The serious results of overcrowding in London will be seen from the following statement showing the

Death-Rates in Five Groups of London Sanitary Districts, Arranged in Order of Density of Population.

	Mean death-rate, 1885-1891.
Districts with density of under 40 persons per acre	15·27
" " 40 to 80 persons per acre	18·04
" " 80 to 120 " "	19·24
" " 120 to 160 " "	22·60
" " over 160 " "	23·88
County of London, 57 persons per acre	19·90

With the necessity for dispersion of the population have come the means by which full facilities for transport can be obtained. Passenger railways with an equal carrying capacity to that of the Metropolitan and District Railway, can now be constructed at one-third of their cost. Electric transit, which has been proved to be efficient and economical, does away with the injurious atmospheric condition hitherto attached to tunnel transit, and thus a serious objection to underground railways is removed.

At the request of the London County Council, Parliament has, in recent Bills for underground railways, removed some of the restrictions by which they were limited to land under roadways. They can now be constructed under private property, and with these improved conditions electric railways can be constructed with less cost and with greater efficiency than was the case with the City and South London Railway. The great and costly disturbance of property by the construction of surface railways, or railways in shallow tunnels, is now avoided by deep tunnels constructed, where necessary, under air pressure. By the use of a shield these tunnels can be driven through soft clay or wet gravel, so that the engineer has only to consider where a railway is wanted, and there, usually, it can be made.

In nearly all directions round London land suitable for building can be found, and much of the land is now of little value. To give effectual relief it will be necessary to drive railways through the city right into the country, so as to obtain access to cheap building land. The underground portion of these railways would be limited to the land already covered with buildings. The railway would be brought to the surface as soon as open ground is reached.

The subject of London railways has received of late years the careful consideration of the most able engineers and experienced railway managers. They appear to have arrived almost unanimously at the conclusion that the establishment of a central railway station, which is found so convenient in smaller cities, is quite impracticable for London, and they are generally agreed that existing terminal stations cannot be brought farther towards the centre of the Metropolis. Not centralisation but distribution is required, and a system of passenger railways for distributing travellers over the whole of London would be welcomed by existing railway companies.

The Joint Select Committee of Lords and Commons appointed last year to consider the electric and cable railway schemes then before Parliament, report respecting these railways that "they are required to relieve the overgrown passenger traffic along the chief thoroughfares, to provide for the natural expansion of London, and to check the congestion of our metropolitan population by facilitating cheap communication outwards to a circumference which tends constantly to recede. More such lines of communication are required with existing suburbs, and there is a growing need of their extension into the country, in order to meet the increasing necessity for the removal of portions of the population to a greater distance."

Mr. Scotter, the general manager of the London and South-Western Railway, in giving evidence before the Joint Committee of Lords and Commons on Electric and Cable Railway, said: "I have come to this conclusion, that the making of the City and South London Railway has altered the whole state of this question. I believe this is only an instalment of many schemes that will be projected in future, especially as the problem has been solved of making an underground railway at about one-third of the cost of the old Metropolitan and District Railways. Something will have to be done to relieve the congested traffic of the streets, and I do not see anything better than these light underground railways, made at a cost of, say, £250,000 per mile, instead of £750,000, which was the cost of the other railways."

It is obvious that the Council need not incur the cost and delay which would arise from considering new systems of locomotion; all that is necessary is to discover the best application of well-known and existing methods. The details for forming a judgment are already provided, and therefore the proposed enquiry need not be costly or prolonged.

The present means of railway locomotion are wholly inadequate, but wherever they are provided at a moderate cost for short passenger traffic those means are largely used. This can be seen by the rush of passengers to and from Broad-street, Liverpool-street, Waterloo, and other stations. This short distance traffic, although in itself profitable, cannot be sufficiently provided for on through railways, which depend mainly on long-distance traffic. Special provision must therefore be made if the people of London are to be adequately accommodated.

It is important that means for locomotion should be provided at the lowest remunerative price. The chairman of the Great Eastern Railway has stated that the traffic between Enfield and Broad-street, at a charge of 2d. for the double journey of 22 miles, is profitable to the company. As this charge meets traffic cost, and pays its share of interest on capital, it may be hoped that a still lower rate, say 1d. on 20 miles, would be found sufficient to meet all expenses, after taking the increased value of land for the cost of construction.

As it is a proved and recognised fact that the construction of railways adds greatly to the value of land, and that the increased value might be made available for the purpose of meeting the cost of constructing railways, the proposed enquiry will probably show that passenger railways might be provided for London without being a burden on the ratepayer, and that the charge for travelling might be so small as to enable all classes to avail themselves of the accommodation. It is, however, obvious that these great advantages can only be secured by equitable arrangements which will secure to the public the increased value imparted to land by such public expenditure.

What occurred as a consequence of the free ferry at Woolwich should be considered in connection with travelling facilities. After this ferry was established, at the cost of the ratepayers, the Council purchased 11 acres of adjoining land for an open space, and for this land they had to pay an additional cost of at least £500 per acre because a free ferry had been established. It is therefore clearly essential that in any plans for affording facilities of transport the increased value of land created thereby should be appropriated to public purposes. The Council's valuer has been asked to give his opinion as to the increased value that would be imparted to land by the construction of a line as proposed through London, radiating 20 miles in each direction from the centre.

The difficulty in relying upon private enterprise arises from the fact that private companies are unable to obtain the increased value of land imparted by railways, which value may accrue to a public authority. This fact, with the great cost of promotion and parliamentary expenses, make it impossible for private enterprise to provide railway accommodation without imposing charges which would be incompatible with full development. It is clearly

desirable that the proposed railways should be laid out on a comprehensive plan, any portion of which might be undertaken, either immediately or later, with due regard to the final results of a complete system.

Omnibuses. The vast increase which has taken place in omnibus traffic shows that the business of omnibus companies is on the whole well conducted, but existing conditions present this anomaly, that while omnibuses, of which there are 2,305 running in London, have free use of public roads, and thus impose heavy burdens on the ratepayer they are not subjected to regulations which are enforced upon other means of transit. Thus we have pirate omnibuses making charges by which the public are entrapped. In the suburbs of London fares are so high that omnibuses wear out the public roads while rendering very little public service. These are matters which clearly require investigation.

Steamboats. The service of steamboats on the Thames is infrequent, costly, and quite unworthy of the provision which has been made for it by the erection of piers in connection with the embankment. Boats at half the present fares and twice as frequent would be a valuable addition to the present means of transport.

Conclusions.—Railways must, for the most part, be relied upon for conveying passengers a sufficient distance to secure proper distribution of population. It is only by railways that passengers can be carried in sufficient numbers and within a reasonable time. The average speed on passenger railways is 2½ times that of tram cars or omnibuses, and the actual cost of transit is much less. Therefore, our chief reliance for relieving London from overcrowding must be upon railways. Tramcars, omnibuses, and steamboats are, however, essential parts of a general system of locomotion, and should be considered in connection with railways. The improvements which have recently been made to the construction of city railways open up opportunities which should be utilised on a general system for passenger railways throughout the Metropolis and adjacent country districts. This work can now be done with very little displacement of property, with a small expenditure for land purchase, and with a beneficial expenditure on labour and materials which will create value and afford useful employment. Recommendations:

1. As railways and tramways involve engineering consideration, we recommend that the subject should be referred to Mr. ——, an experienced engineer at a fee not exceeding £ ——, to report: (*a*) As to the best routes for passenger railways and tramways to provide means of communication between all parts of the Metropolis and adequate connection with surrounding country districts, having due regard to population and convenience of construction. (*b*) As to the cost of constructing such railways and tramways, taking into account the latest improvements. (*c*) The cost of working such railways and tramways and the fares which should be charged. (*d*) In conference with the valuer of the Council to report as to the cost of land at various points suitable for building, and the effect of such railways upon the value of land, both in London and in the country.

2. Omnibuses and steamboats should, we think, be made the subject of an enquiry by an able accountant or inspector, in order to ascertain existing routes and fares, and to suggest such regulations as may be desirable for the consideration of the Council.

3. These reports could be obtained for the sum of £500, which amount should be appropriated to this enquiry from the £1,000 which the Council, under the Act of last session, are authorised to expend at their discretion.

This report, together with the recommendations contained therein, has been adopted by the Council.

LEGAL INTELLIGENCE.

ELIESON ACCUMULATOR COMPANY v. THE EARL OF GALLOWAY.

The hearing of this case, which was referred to in our last issue, was resumed and concluded on Wednesday before Mr. Justice Kennedy, without a jury, in the Queen's Bench Division. It will be remembered that this was a claim for £400 for money payable on the allotment of shares to the defendant in the plaintiff company.

Mr. Clavell Salter appeared for the plaintiff company; and Mr. Lockwood, Q.C., and Mr. Pollard for the defendant.

The plaintiffs' case was that the defendant applied for 2,000 £1 shares in the company, and paid £100 as a deposit of 1s. a share on application. The shares were duly allotted, and £400, now sued for, then became due.

Mr. Watson Smith, the promoter of the company, was called and examined and cross-examined at some length as to the circumstances of the case.

Mr. Lockwood, for the defence, contended that in August, 1892, the defendant handed to Mr. Smith £50 to be held by him as deposit for shares in a prospective company, but only to be applied for, by Mr. Smith as the defendant's agent, according to a prospectus which stated that a contract had been entered into for the purchase of patents for £6,000 and if certain conditions were fulfilled. Among those conditions was one that *bonâ fide* applications from persons other than Lord Galloway should be received for shares to the extent of £2,000. On October 13, 1892, the defendant wrote saying he would not proceed unless his conditions were fulfilled, and appointed a meeting with Lord Sackville Cecil for the next day. On the morning of the 14th, and before that meeting was held, Mr. Smith now alleged that he had held a meeting of the company in his office and proceeded to registration and allotment. That allotment could not be relied on as a *bonâ fide* allotment. As a matter of fact, the patents never were acquired, and the company was really no other than Mr. Smith; and whatever instructions were given by the defendant to Mr. Smith, they were revoked on October 13 or October 14.

Mr. Salter submitted that after Mr. Smith had made an application the authority could not be withdrawn. Even if the authority was withdrawn, the withdrawal was not communicated to the company.

Mr. Justice Kennedy, on Wednesday morning, delivered judgment, and while stating the facts, said the plaintiff company was apparently formed for the working of an English patent which was said to be the best accumulator for electrical purposes and especially for the locomotion of tramcars. In July, 1892, the defendant seemed to have been easily drawn into the hope that it would be a success, and exhibited a trustfulness which must have been pleasing to the promoter. The defendant somehow got on the register of the plaintiff company, and he did authorise Mr. Watson Smith to apply on his behalf for shares if there was then a genuine company which was in a position to do what it was formed to do and carry out its purposes as represented. Now Watson Smith pushed the concern and was the foundation of the company, and then Mr. Elieson was added to him; and this was confirmed by Mr. Pallas, who also had a share in the company. By September 24, £100 had been paid to Mr. Smith by Lord Galloway. Was it a payment to himself as a promoter or for the purposes of the company? Perhaps both, but it passed into his private banking account. At the interview of October 13 with the defendant, the chairman, Mr. Watson Smith, stated that the company was registered; but there was a conflict as to what took place afterwards, and it was left in some doubt by the defendant, and he could not find that then the defendant stated that he meant to withdraw unless the conditions he required were fulfilled. But he regretted he could not trust the version of the plaintiffs' witness in this and in other matters. He did not believe that the defendant pressed for allotment, and he denied it positively. This was borne out by what took place at the meeting at Lord Sackville Cecil's on the following day, and a letter was written on October 17 by Mr. Drew, Lord Galloway's agent, corroborating this view, that W. Smith was not to exercise his authority to apply for shares till certain conditions were fulfilled, and that he waited to see if a company had been registered. The allotment was alleged to have taken place on the 14th, and the minute book was said to have been written up a day or two later, but the secretary ought to have immediately notified the fact to the allottees. But no such notice was given till October 20, after Mr. Drew's letter of the 17th to the secretary. The plaintiffs' counsel had treated the case with equal frankness and ability and it seemed that the defendant told W. Smith that he did not mean to have any interest in the company unless his conditions were fulfilled. But Watson Smith was silent on any allotment, and he could not trust that witness when in conflict with two or three credible witnesses, especially after the matter of a statement that he had paid a sum of £300 on account of Lord Galloway "at some inconvenience" when no such sum turned out to have been paid. Watson Smith attended at the interview at Lord Sackville Cecil's as chairman of the company, and said nothing of the allotment to the defendant, which he thought honour and good faith would have required. Why could he not have said, "Why, you are a shareholder already, made so yesterday on my application?" Any application for shares according to the terms of the agency could only be made if the company fulfilled its objects. Was it, then, a full going concern? He thought not. A company had been registered by Elieson's wish and advice, but there was nothing effectual: it had not been confirmed by Pallas: nothing enabling the company to call on Elieson to sell his patent to them. They went on probably with the object of getting more money from Lord Galloway, and they were not in a position honestly to say that they had carried out the provisions of the prospectus, though he assumed that they could call on Elieson for the fulfilment of his agreement. The company kept no bank book, and had no banking account: except two gentlemen, all the members were the nominees of Watson Smith. Was this, then, a company in which the defendant authorised him to apply for shares? He thought not. Mr. Elieson did not subscribe, and the company had nothing, no right to any contract, and had not the necessary essentials of a company. There was then, a withdrawal before the acceptance of the shares notified by the defendant to the plaintiffs before the posting of the secretary's letter. It was said that the notice of withdrawal of October 14 was given to W. Smith and not the company; but he thought that gentleman attended the meeting as a director or agent for the company. Mr. Dawes said he then represented the company, and that they discussed the terms on which Lord Galloway would become interested in the concern. He found there was a notice to the company that the defendant would not take an interest therein except on certain conditions, which were not carried out. But if there was an authority, then there was sufficient evidence of a revocation. The case cited by the plaintiffs' counsel in 7 Chan. App., 161, was no doubt binding on a court of first instance. But in every case due regard must be paid to the character of the director, notice to whom was there held not to affect the company. There would be judgment for the defendant on the claim, with costs, and an order that his name be expunged from the register. But as to his counter claim for the two sums of £50, as these had passed into Watson Smith's private account and had never come into the possession of the plaintiffs, there would be judgment for them as to that, with costs of that issue.

COMPANIES' MEETINGS.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.

Mr. W. S. Andrews presided over the ordinary general meeting of the Western and Brazilian Telegraph Company, Limited, held last week at Winchester House, E.C.

In moving the adoption of the report, the **Chairman** said that the total earnings for the half year amounted to £79,373, as against £84,021 in the corresponding half year. The working expenses amounted to £43,424, as against £39,140, or an increase of £4,283, which was principally due to the cost of the extra staff and arrangements required to work efficiently the duplicated and duplexed line. The object of the loop cables was to avoid interruptions and so keep the traffic together, and to enable the Company ultimately to do with one ship. Those objects had been secured. Since the cables were completed between Pernambuco and the River Plate there had not been one single interruption. The work had been done in such a satisfactory manner that the volume of traffic had increased 12½ per cent.; but that had produced less profit, owing to competitive rates, shifting of traffic, and bad exchange. They only required the restoration of order in Brazil and the re-establishment of the exchange upon a reasonable footing to enable the Company to again become remunerative. Under all the circumstances, the Board did not feel justified in recommending a dividend. At the present rate the receipts for the current half-year would be £9,000 less than those of the period under review.

Mr. C. W. Earle seconded the motion, which was adopted.

ELMORE'S PATENT COPPER DEPOSITING COMPANY.

The ordinary yearly meeting of Elmore's Patent Copper Depositing Company was held on Wednesday at the Cannon-street Hotel, Mr. J. Todhunter presiding.

Mr. J. L. Langmead, the secretary, presented the report of the Directors, which is given in another column.

The **Chairman**, in moving its adoption, first referred to the difficulty the new Board had had in arriving at the real position of the Company's finances owing to the way in which the accounts had been kept. He believed now, however, everything had been written off which ought to be written off. The Company had carried out every order which had been demanded, but owing to the coal strike this had only been done at considerable cost. The Wire Company had been a source of great anxiety to the Company. So long as they could use the Wire Company's furnaces all would be well, but the finances of that company were in such a condition that they might pass out of the control of the present Board at any moment. Mr. Atkinson, the chairman of the Wire Company, would probably explain certain arrangements which were in progress which might render any change unnecessary. The works were now in good order, and the Company would be ready to execute orders as soon as they could get the coal. They had actual orders to the extent of 65 tons of finished output, a large proportion of which had come to hand during the last six weeks. He was not at liberty to go into details, but there seemed to be an opinion that the Company's process was the only process of coating the tail shafts of big steamers, and in this way a trade seemed to be opening out to the Company apart from the trade which they had previously expected. The coal strike had cost the Company between £3,000 and £4,000; and this, together with the sum due from the Wire Company and other liabilities which the Directors were not aware of when they took over the management of the company's affairs, because they were not in the books, had reduced the working capital of the Company to £4,000, a sum which was absolutely inadequate to provide for the working of the concern. It remained for the shareholders to say whether they would provide the further capital for carrying on the works. What the Directors proposed was that debentures should be issued to the extent of £10,000, and his co-Directors and himself, to show the confidence they had in the concern, proposed to subscribe £1,300 of this. They suggested that the debentures should bear interest at the rate of 6 per cent., and proposed to make them redeemable at six months' notice at the rate of £102 for every £100 debenture. The share capital would have to be written off sooner or later, and it would be a great convenience to appoint auditors resident in Leeds. In conclusion, the Chairman said the shareholders must not go away with the impression that the Company was in difficulties. They had money in hand and copper to go on with, but they had not sufficient money or copper to execute the orders placed with them and those they had in prospect.

Mr. J. W. Dale seconded the adoption of the report.

Mr. J. J. Atkinson, one of the largest shareholders in the Company, and the chairman of the Wire Company, stated that the latter company had only one pressing claim—the claim of their bankers. On Monday week he tendered to the bankers the money they were entitled to, and he believed that in the course of a few days he would be able to give the Depositing Company the copper he had promised them. Like the Chairman, he thought the two companies ought to be amalgamated.—The report and accounts were adopted.

Copper.—The variations in the value of good merchantable copper have again been slight during the past fortnight, from £42. 1s. 3d. to £42. 10s. for cash, prices fluctuating more or less each day.

BUSINESS NOTES.

Northallerton.—The linoleum factory is now lighted by electricity.

Leyton.—The Local Board are seeking powers to supply electricity in the district of Leyton.

Grimsby.—The Town Council have decided to apply to the Board of Trade for a provisional order.

Monmouth.—The Corporation are applying for powers to supply electricity for public and private purposes.

Western and Brazilian Telegraph Company.—The receipts for the week ended November 17 were £3,115.

Newcastle.—The Electric Lighting Committee of the Town Improvement Committee has been reappointed.

Woolwich.—The District Board have under consideration a proposal to light the baths and Town Hall by electricity.

Northampton.—The Town Council have granted the application of Messrs. Smith Bros. to erect three telephone wires.

Upton.—It is proposed by the Cheshire County Council to light the projected new asylum at Upton by electricity, at a cost of £2,000.

Shrewsbury.—The Shropshire Electric Light and Power Company are applying for powers to supply electricity for public and private purposes.

West India and Panama Telegraph Company.—The receipts for the two weeks ended November 15 were £83 more than for the corresponding period.

Telephone Press, Limited.—This Company has been registered with a capital of £3,500 in £1 shares, to carry on business as printers and publishers.

Aberdare.—Mr. J. C. Howell, of 24, Queen Victoria-street, E.C., is applying for powers to supply electricity in a certain portion of the area of the Local Board.

Post Office Lighting.—The new General Post Office building in Aldersgate-street is about to be wired by the staff employed at St. Martin's-le-Grand. About 2,000 lamps of 16 c.p. will be required.

Paddington.—The Baths Commissioners have expressed their admiration for the way Messrs. Dawson and Hammond, of John-street, Edgware-road, have completed their work of lighting the hall by electricity.

Sydenham.—We understand that Messrs. Drake and Gorham have been entrusted with the rewiring of the entire installation at Westwood House, Sydenham, for Mr. C. J. W. Rabbits, where there are about 200 lights.

Dixon Patent Fog-Signal Company, Limited.—This Company has been registered with a capital of £4,000 in £50 shares, to acquire and turn to account certain patents relating to improvements in apparatus used in fog signalling.

Sutton (Surrey).—A further report by Mr. E. C. de Segundo is under the consideration of the Local Board. Mr. de Segundo suggests that it might be advisable for the Board to establish a small installation as a beginning.

Harrow.—The Local Board have decided to apply for a provisional order for supplying the district with electric light, and have also under consideration the erection of public baths and the extension of the boundaries of the district.

Personal.—Mr. F. Leonard, who for the past 25 years has been manager to Messrs. S. Pontifex and Co., gas, water, and electrical engineers, of 22, Coleman-street, has now acquired the entire business. He intends to retain the present title.

Derby.—The following have been appointed members of the Electric Lighting Committee of the Town Council: Aldermen Bemrose, Heathcote, Leech, Sowter, and Woodiwiss; Councillors Bottomley, Butterworth, Harrison, Haslam, Marsden, and Stone.

Camberwell.—The Vestry intend to apply to the Board of Trade for a provisional order authorising them to supply electricity within so much of their parish as is not already authorised to be supplied by the Crystal Palace District Electric Supply Company.

Ander's Telephone Company, Limited.—This Company has been registered with a capital of £10,000 in £1 shares, to acquire certain patents relating to improvements in telephones, and to carry on business as electrical engineers and telephone manufacturers.

Norwich.—The Town Council have decided to expend a sum not exceeding £40 for placing at the city lunatic asylum the electric light mains in culverts underground, and a sum not exceeding £40 for providing and fixing a suitable switchboard and connecting the dynamos.

Volk's Electric Railway.—We understand that Messrs. Johnson and Phillips are supplying for this railway a 20-kilowatt special heavy type Kapp dynamo, and that Messrs. Tangyes, Limited, are providing a 20-h.p. gas-engine, fitted with self-starter and all recent improvements.

Chatsworth.—The electric lighting of Chatsworth, which was entrusted to Mr. Bernard Drake by the Duke of Devonshire, has been successfully completed, and the whole plant started up without a hitch of any kind. We may shortly describe this installation in detail, it being unique in many respects.

City and South London Railway Company.—The receipts for the week ending November 19 were £879, against £899 for the same period last year, or a decrease of £20. The total receipts for the second half-year of 1893 show an increase of £181 over those for the corresponding period of 1892.

Agency —We learn that Mr. J. D Baillie, late installation superintendent for Messrs. J D F. Andrews and Co , London, S W , has been appointed Yorkshire representative for Messrs. C. A. Parsons and Co , electrical engineers, Newcastle upon-Tyne, with offices at Peacock's buildings, Park row, Leeds.

The Royal Exchange —The ceremony of turning on the electric light at the Royal Exchange, which work has been carried out by Messrs. J. G Statter and Co , was announced to take place yesterday. The Lord Mayor of London was to personally perform the ceremony of switching on the light for the first time.

New Swindon - Mr. Hamp reported at a recent meeting of the Local Board that the Electric Lighting Committee had met and recommended that Mr. Aldridge, electrical engineer, of Westminster, should be instructed to prepare a report on No. 1 district, together with an estimate of the cost. This was agreed to.

Telegraph Construction and Maintenance Company, Limited. The directors notify the holders of the £150 000 £5 per cent. debentures that they intend to renew the existing debentures, which mature on January 1, 1894, with debentures to an equal amount, to mature on January 1, 1899, and upon which interest will be payable half yearly at the rate of £5 per cent. per annum.

Folkestone.—The question of reappointing the Electric Light Committee of the Town Council was considered at a meeting of the latter last week Councillor Thompson contended that it had not been dissolved, and that it would remain in existence until the report was made The Mayor decided that the committee was still in existence After some discussion the Electric Light Committee was reappointed.

Poplar -The Works Committee of the District Board of Works have recommended that Mr. W. H Preece should be invited to report, at an expense not exceeding 50 guineas, upon the question of electric lighting and the application of the Poplar Electric Lighting Order, 1893, to the district, with particulars of the cost of the installation of the light. The recommendation of the committee has been adopted

Tenders for Dublin.—The Corporation of Dublin invite by the 14th proximo tenders for the extension of the buildings and the supply and erection of additional plant at their central station, Fleet-street Dublin Plans may be seen and specifications and forms of tender obtained, at the office of Mr. Spencer Harty, C.E , city surveyor City Hall, Dublin, on payment of one guinea, which will be returned to all persons sending in a *bonâ fide* tender.

Tenders for Barnet. The Barnet Local Board, as will be seen from our advertisement columns invite applications from those willing to take a transfer of, and to undertake and carry out, the powers granted by the Barnet Electric Lighting Order, 1893 Applicants are to state the system of lighting proposed, the charge for lighting the public lamps, and the terms upon which they would give the local authority the option to purchase the undertaking.

York.—Tenders are invited for the following articles during six months ending June 30, 1894, delivered carriage paid at the telegraph stores at York, for the North Eastern Railway Company: (1) telegraph apparatus, (2) telegraph wire and line stores. Forms of tender may be obtained on application to Mr. Graves, Telegraph Department, York, and tenders must be sent to the secretary, at York, sealed and marked "Tender for Telegraph Stores," by December 5.

City of London Union.—The Infirmary Committee reported on Tuesday with regard to the expediency of lighting the infirmary with electricity, and recommended that the Board should give permission to their consulting an electrical engineer, at a fee not exceeding £10 10s , to advise the committee as to the installation of electric light, and that the committee report the result of their consultation to the Guardians. Mr. Lile moved the adoption of the report, and this was carried.

A New Cable.—The Commercial Cable Company have signed a contract with Messrs. Siemens Bros. and Co. for the manufacture of a new Atlantic cable, to be laid between Ireland and Nova Scotia in the ensuing spring This cable, which will be the third one owned by the Commercial Cable Company, will be 2,200 miles in length, and is to be made to a specification ensuring greater carrying capacity than any cable of the same length It will also be of special strength in order to resist ships' anchors in fishing waters.

Dublin.—At a meeting of the Corporation on Friday, Alderman Dillon moved several amendments to standing orders, and to add a new standing order as follows: "The Lighting Committee has charge of all matters relating to the lighting of the city, and all the powers hitherto vested in the Paving and Lighting Committee in connection with lighting matters, the quality and measurement of the gas supplied to the citizens, as well as the management and all matters relating to the electric lighting undertaking of the Corporation." The motion was not carried.

Faversham.—An installation of the electric light has been fitted on the premises of Mr. Henry S. Tett, ironmonger, Market street The system of wiring adopted is Andrews's patent. The plant consists of an 8 h.p. Otto gas engine, a Crompton continuous-current dynamo, and a battery of accumulators. The last mentioned are charged during the day, and will supply some of the lamps by themselves, or, if all the lights are required at once, the accumulators and the dynamo are run together, the former acting as a regulator and keeping the light steady Over 60 lamps, of 8 c.p., 16 c.p., and 50 c.p., have already been fixed, and others are in course of preparation. Mr. Tett is the agent for Faversham and Sittingbourne for Andrews's system of wiring.

Chichester.—As mentioned in our last issue a report on electric lighting has been presented by Councillor Prior to the Sub Committee of the Lighting Committee of the Town Council. Mr Prior states that he had consulted an electrical engineer upon the probable cost of lighting the town by electricity. The engineer had visited the city and gone fully into the matter, and had sent a report on the subject. The conclusions he arrived at were that the initial cost of lighting the principal streets of the old city with electricity would be from £12,500, as a low estimate, to £14,000 as a high one. The annual expenditure would be about £2,791. The revenue should be about £3,300.

Wallsend.—The Wallsend, Willington Quay, and Howdon Joint Hospital Board have considered a letter from the medical officer asking the Board to take the necessary steps to get gas laid on at the hospital. The Clerk mentioned at a meeting of the Board, that estimates of the cost of lighting the hospital by gas and by electricity had been obtained In respect to the former, the cost of laying a 2in. main would be £100, and of a 3in. main £150. Another estimate for the gas was £150 for 3in mains and £60 for the necessary fittings. An estimate for lighting the hospital by electricity, including complete lighting, installation, etc , for 50 separate lights was £138. 10s. by steam, and £184 by oil The Rev. J Hughes moved that the hospital should be lighted with oil, and this was adopted

Oswestry.—The Town Clerk mentioned at a meeting of the Town Council and Local Board last week that a notice for the provision of an electric light supply had been applied for for Oswestry by the Oswestry Electric Lighting and Power Company, and that he thought it would be well to refer it to the committee that had already been considering it for further consideration and report. Before December 20, the draft provisional order was to be deposited in various places in London, and also with himself, for perusal by the Council The Council would then have a right to go into the matter, and make any objections or observations to the Board of Trade they might think necessary until January 15 next year. There would thus be ample time for the consideration of the matter. At the present time they had no data to go upon, because the draft provisional order had not been seen by anyone in the employ of the Town Council. The matter was referred to the committee.

Belfast —The lighting of Queen's Quay is about to commence. The question of the use of electric light had been under the consideration of the Harbour Commissioners for a long time, and a practical step was taken in the matter towards the end of last year, when the tender of Messrs. Siemens Bros. and Co. was accepted for lighting the Queen's Quay, the Abercorn Basin, and the Hamilton Graving Dock. The construction and erection of the installations are superintended by Mr. George Combe, electrical engineer, Belfast, on behalf of the Commissioners. The total distance between the extreme ends of the circuit, beginning at the Queen's Bridge, is about 1,000 yards, the generating station being situated about midway on the Queen's-road, opposite the Abercorn Basin. The lamps comprise 19 arc lamps, thoroughly protected from the weather, and provided with opal or fluted wired globes suspended overhead on wrought-iron lattice masts 40ft. in height, and fitted with hoisting gear of wire ropes for lamps. The three dynamos in use will be worked by a high pressure non-condensing engine, capable of giving 40 actual horse power.

Hanley.—The scheme for lighting this town by electricity is being pushed on by the committee in whose charge the matter is placed, and there seems a probability of the town reaping the advantage of the improved system of lighting early in 1894 Mr Joseph Lobley, borough engineer and surveyor, has informed a Press representative that the work was progressing satisfactorily. The building of the chimney shaft has just been completed, and the cap and lightning conductors are now being placed upon it. The boiler house and engine and dynamo rooms are nearly in a state of completion, and the work of roofing them in is in progress, whilst as soon as this is finished the engines and dynamos, which are already made and ready for fixing, will be put in. The seven-ton travelling crane has also been made, and is quite ready for erection. With regard to the electric mains, those for actual distribution throughout the whole of the compulsory area, which comprises the central portion of the town, have been laid. The committee have drawn up and will shortly publish a pamphlet on the subject, in which they will inform the public that the work is being rapidly pushed forward, and express the hope that very early in the coming year they will be able to supply the current.

Elmore's Patent Copper Depositing Company.—In their report for the year ended June 30, the directors state that a mistake was made in the allotment of preference shares, 195 of which were not taken up After stating that all the efforts of the directors were frustrated by the coal strike, the report states that on the question of orders the books show orders on hand for 126 048lb., against 28 391lb at June 23 "A steady trade is being done in coating hydraulic rams and building up calico rollers. The delay caused by the coal strike has been very hard on the resources of the Company, which were, at best, barely adequate, as shareholders will remember; besides which, several considerable payments have had to be made to meet liabilities incurred by the old Board, and which did not appear in the books and could not have been included in the estimates submitted by the present directors; consequently, if a large trade is to be done, more money will be required to restore sufficient capital for furnishing the £10,000 worth of copper originally stated as being necessary. It will be evident that before dividends can be paid, even on the preference shares, it will be necessary to write down the value of the ordinary shares so as to wipe off the amount standing to debit of profit and loss. As an extraordinary general meeting of the shareholders

will be required to carry out the necessary resolutions, the directors intend taking the needful measures for that purpose." The loss for the year is £13,655, which, added to the debit balance of £7,862 as at June 30, 1892, makes the total loss £21,517.

Telephony at Liverpool. — Telephonic communication has recently been established for the Corporation connecting the offices of the water engineer in Dale-street, Liverpool, with the water supplies of Lake Vyrnwy, the Rivington Reservoirs (North Lancashire), and the houses of the reservoir keepers and walksmen along the lines of aqueducts. The work has been carried out to the specification of the city water engineer (Mr. J. Parry, M.Inst.C.E.) by Messrs. W. A. Shaw and Co., electrical engineers, of Warren-street, Stockport, under the personal supervision of the partners. The system is entirely on the metallic circuit principle, and the wires are carried as nearly as possible along the lines of aqueducts. The total distance of lines as laid is about 115 miles. The line wire is throughout of 12½ copper, and about 16½ tons of this wire have been used on the work, as also about 2,300 poles and 5,000 insulators; 5½ miles of line have been laid underground between Prescot and Oswestry, the cable being the lead-covered telephone cable of the Fowler-Waring Cable Company. They are in all 26 stations connected on the telephone system. The instruments used are of the Consolidated Telephone Company's Gower-Bell transmitters and bell receivers, with magneto signalling bells. In connection with the signalling arrangements, Messrs. Shaw have introduced various improvements not before associated with such work. In addition to the telephonic communication, there are also alarm contacts to valves and for overflows, ringing bells at the nearest signalling station.

Result of Dewsbury Tenders. — For works required in erection of an electric lighting station within the borough, for the Corporation (Mr. Henry C. Marks, A.M.I.C.E., borough engineer):

M. Scott, Earlsheaton, near Dewsbury	£3,418	4	4
B. Graham and Sons, Huddersfield	3,423	4	0
E. Chadwick and Sons, Staincliffe, Dewsbury	3,562	0	0
C. Whitehead and Sons, Ravensthorpe, near Dewsbury	3,614	11	2
Crabtree and Denton, Dewsbury	3,695	18	0
W. and J. Milner, Mirfield	3,766	5	0
Holme and King, Liverpool	3,843	9	3
W. Scott and Son, Dewsbury	3,940	10	0
J. E. Johnson, Leicester	4,160	14	0

For extra only for glazed-brick facing in engine-room, and for extra only for Helliwell's patent glazing in roofs:

	Glazed brick.			Glazing.		
Scott (accepted)	£140	0	0	£28	9	6
Graham	177	10	6	25	17	6
Chadwick	236	14	0	21	10	0
Whitehead	167	13	3	28	10	0
Crabtree and Denton	147	18	9	31	10	0
Milner	236	14	0	31	10	0
Holme and King	118	7	0	31	1	0
W. Scott	240	0	0	28	9	3
Johnson	177	10	6	30	0	0

Kendal. — When the question of the proposed purchase of the gas and water undertakings was discussed at a meeting last week of the Town Council, Councillor Hargreaves said he blamed the committee for not calling in the services of an electrical engineer to advise with them before offering to purchase, and so far as he understood, the committee never even considered the question of gas *versus* electricity. At the last Corporation meeting he called attention to the question of electricity and gave statistics and figures to show that in Kendal the electric light could be produced as cheap as gas—namely, 3s. per 1,000ft. He contended that for an expenditure of £25,000 they could put in a steam electric light installation that would supply the town, both public and private lighting, with as much light as at present, at as cheap a cost as gas, and leave a profit. He strongly advised them to drop at once all proceedings for purchase and let the directors carry on the good work of giving pure water. They would give a better supply sooner and much cheaper than the Corporation could. While they were improving the water supply let them put in the electric light. They had powers to this at a cost of about £100, whereas it would cost them £1,500 to £2,000 to get parliamentary powers to buy the gas company. If they did not do this some private company would do it, and they would have another monopoly set up in their midst. He moved that negotiations for the purchase of the gas and waterworks be at once dropped, and that steps should be at once taken to supply the town with the electric light. Councillor McKay seconded, but the motion was rejected.

Charges for Current at Manchester. — The following are the rates and methods of charge for the supply of electricity by the Manchester Corporation: The Corporation will, at the option of the consumer, charge for the supply of electricity either at the rate of 8d. per unit as measured by meter, with a minimum charge of 13s. 4d. per quarter, or at the rate of £3 per quarter for every unit per hour consumed when all lamps or other consuming devices are in use, and 2d. per unit as measured by meter; that is to say, at a fixed charge of 4s. per quarter for each 16 c.p. lamp, and 2d. per unit as measured by the meter. If desired, the Corporation will supply a meter or meters at a rental of 10 per cent. per annum on the cost of such meters. The Corporation have under consideration the adoption of a method of charge by which the use of a meter will be rendered unnecessary, thereby avoiding expense to small consumers. If the lamps and other consuming devices are used to such an extent that their total use amounts to less than 480 hours per annum of the whole of the lamps and other consuming devices, it is more economical to adopt the charge of 8d. per unit; if, on the other hand, the total use amounts to more than 480 hours per annum, the charge of £3 per quarter and 2d. per unit will be less. A Board of Trade unit of electricity will supply 15 16-c.p. lamps or 30 8-c.p. lamps for one hour, if the lamps are suitable. A Board of Trade unit of electricity will supply two arc lamps of 10 amperes for one hour. A Board of Trade unit of electricity will, with a good motor, give more than 1 h.p. effective for one hour. Ten units, with incandescent lamps of 16 c.p., produce an amount of illumination about equal to 1,000 cubic feet of gas.

Swansea. — Alderman Tutton, in moving the adoption of the minutes of the Property Committee of the County Borough Council a few days ago, referred particularly to the following minute: "The town clerk informed the committee that several companies had given notice of their intention to apply to the Board of Trade for a provisional order for the supply of electricity in this borough. Resolved, that the assent of this Corporation be refused in respect of each application, and that a petition under the common seal be presented to the Board of Trade requesting that Board not to sanction any order that may be applied for, it being the intention of the Corporation to at once enforce the provisions of the Swansea Electric Lighting Order, 1889; also resolved, that the sub-committee be reappointed." Alderman Tutton having explained the position of the committee, the Town Clerk, in reply to questions, said the position was this—that the Corporation could no longer sit down and allow their powers to become inoperative. If they allowed it to go forth to the Board of Trade that they merely sought for powers to allow them to remain dormant, the Board of Trade was very likely to set them aside, and grant one of the applications from private firms. What was wanted now was an assurance to the Board of Trade that they were serious in regard to electric lighting, and that they would either proceed at once to carry it out themselves or would commission a firm to do it. The three years had passed and they must do something. Alderman Martin said it was only right that the Board of Trade should know that they had already done something in the matter. They entered into communication with a firm before they got the order; but after they got the order that firm doubled its estimate—— Alderman Tutton: And wanted a contract for 21 years instead of seven. Alderman Martin said that was so. If the firm in question now proved more reasonable, he was sure the Corporation would not be disinclined to enter into a contract in the matter. The minutes were carried. The Swansea electric lighting order being about to expire, Messrs. Crompton and Co. Limited, are about to step into the breach and ask the Board of Trade for a provisional order to light Swansea by electricity.

Lighting at Nottingham. — Preparations for the installation of the electric light, under the Nottingham Electric Lighting Order, 1890, have reached a definite stage. Acting under the advice of the borough electrical engineer, Mr. Herbert Talbot, the Corporation sanctioned a scheme which included the erection of a central station on the site known as "Holborn Villas," between Talbot-street and Wollaton-street, and the laying of mains in the "compulsory area" and in two other streets which formed convenient connections between streets in that area. Practically, the whole of the central portion of the town will be traversed by these mains. The mains are being laid on the Callender-Webber system. The ordinary work of excavating, etc., is being carried out by Corporation employés, but the contract for the more special work has been placed with Callender's Bitumen, Telegraph, and Waterproof Company, Limited, who are to maintain the system for three years, and at the expiration of that time hand it over to the Corporation in a condition equal to passing a test laid down in the specifications. At the central station in Wollaton-street, building operations were commenced about August, and though even now a general idea may be formed of what it will eventually be, some delay has taken place owing to the failure, on account of the coal trade dispute, to obtain glazed bricks. Following Mr. Talbot's suggestion, the Corporation have decided that the buildings shall be large enough to contain plant for supplying 13,000 8-c.p. lamps, but for the present plant for 10,000 lamps will be put down. The buildings are so designed, however, that should necessity arise they can easily be extended. This chimney, when erected, will be 160ft. in height. The three boilers with which the building will be fitted at present are by Mr. Edwin Danks, of Oldbury, Birmingham. Green's economiser has already been fitted, and in connection with this Berryman's feed-water heater will also be used. The contract for the engines and dynamos is being carried out by Messrs. Siemens Bros. and Co. The engines are of the Willans type. The station, when finished, will be creditable to the Corporation and the contractor, Mr. F. Messom, of Nottingham. The method to be used is the low-pressure continuous current three-wire system. It is anticipated that the work will be completed by April next, and people in business along the streets in which the mains are being laid will be able to have the electric light supplied to them forthwith. A number of applications for the light have already been sent in. It has not been decided by the Corporation that the streets shall be lighted with electricity. That will probably form the subject of future consideration. The cost of the light to the consumer has not yet been fixed. The total cost of the scheme will be about £45,000. The site of the buildings cost £10,175, and the capital outlay on the buildings, plant, mains, and installation will be about £34,000 or £35,000.

Guildford. — A public meeting was held last week to consider the desirability of introducing the electric light. Alderman J. Mason, J.P., who presided, said that he had hoped that electric lighting would have been introduced by the Corporation, and the question was referred for the consideration of a committee. The

expense, however, according to their report, would have been so enormous that he did not think the public would have approved of the Corporation incurring it he believed it was £20,000, or something of that kind; and he did not think that the Corporation would in the present position of affairs have been justified in going to anything like that expenditure. Mr. Sidney Sharp (who was called on by the chairman) said that the object of the meeting was to interest them in the establishment of an electricity supply station The cost of a provisional order was from £150 to £250 it varied according to whether there was any opposition or not but one must be prepared to go to the latter sum if necessary The formation of a company would probably cost another £150, and the object they had in view that evening was the provision of the £400 with the ultimate prospect of forming a Guildford Electricity Supply Company He did not see why a company in Guildford, which has a very good business centre, should not pay dividends as well as companies to which he referred. He had stated at a previous meeting that a sum of £10,000, roughly would be required for the erection of a station for 4,000 8 c.p. lamps He had been told since that that possibly was rather a large sum to raise for a new undertaking If that were so, they would be content with a station of less capacity, but the reason he suggested the above number was to be prepared for extensions in the future It was desirable, where possible, that the buildings and the mains should be made with a view to the future, though the other plant could be added to according to the requirements He thought that those who were willing to put their money down for obtaining the parliamentary powers should be entitled to remuneration in proportion to the risk they ran, and founders' shares were probably the best way to meet that. After a dividend of 5 per cent had been paid on the ordinary shares founders' shares should take a certain proportion of the rest of the profits Mr Sharp pointed out that, in addition to the electricity required for lighting purposes, it would no doubt be a great advantage in many places as a motive power, for which it could be used very economically. If the application for a provisional order was not proceeded with immediately it would have to be postponed for a year, and, therefore, if possible something definite should be done that evening towards ensuring that the application to the Board of Trade should be carried through Councillor Salsbury said that some time or other there was bound to be an electric lighting company in Guildford, and he had not the slightest doubt but that if a company were started it would pay, because he was quite certain that the majority of the tradesmen, after they saw the advantage of the electric light, would become purchasers of it If a provisional order were once obtained, he did not believe there would be much difficulty in floating a company. With the view of testing the opinion of the meeting, Mr. C. Holden proposed, and Mr. A. F. Asher seconded, a resolution in favour of electric lighting being introduced into the town, and this was carried. A committee was then formed to further promote the scheme.

PROVISIONAL PATENTS, 1893.

NOVEMBER 13.

21589. **Improvements in electrical signalling, recording, and detecting apparatus.** Thomas Davis and Edward Davis, Lord street, Liverpool

21592. **Improved means of obtaining electrical contacts, disconnections and reversing currents for operating electrical indicators or signals.** Hugh Reid, Belmont, Springburn, Glasgow (Complete specification)

21609. **A method and apparatus for the production of light by electric and electromagnetic oscillations and vibrations** Alfred Rene Upward, 150, Holland-road, Kensington, London

21619. **An electro deposit of zinc.** Joseph Nixon, St. John's-square, Clerkenwell, London.

21624. **Improvements in or connected with electrical storage batteries** Edwin Augustus McLachlan, 11, Furnival-street, Holborn, London.

21628. **Improvements in telegraphy.** Patrick Bernard Delany, 24, Southampton buildings, Chancery lane, London. (Complete specification)

21629. **Improvements in cable and submarine telegraphy.** Patrick Bernard Delany, 24, Southampton buildings, Chancery lane, London. (Complete specification.)

21630. **Improvements in telegraphy.** Patrick Bernard Delany, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

21631. **Improvements in electrolysis and in apparatus therefor.** William Hay Caldwell, 24, Southampton buildings, Chancery lane, London.

21637. **An automatic electric signal for tramways and the like** Henry Oakden Fisher and William Walter Phillips, 22, Southampton-buildings, Chancery-lane, London.

NOVEMBER 14.

21714. **Improved electric exchange systems with apparatus therefor, applicable also for telegraphic and electric typewriting purposes** Samuel Dickinson Williams Moorlinch House, Clytha Park, Newport, Monmouthshire.

21716. **Improvements in the means of producing electric light.** *James Clegg, Brampton, West Norwood, London.*

21734. **Improvements in dynamo-electric machines** David Henry Wilson, 321, High Holborn, London. (Complete specification)

NOVEMBER 15.

21812. **Improvements in electrical means of advertising.** Alfred Rene Upward, 150, Holland-road, Kensington, London.

21850. **Improvements in voltameters.** Henri Adrien Naber, 4, South street, Finsbury, London. (Complete specification.)

NOVEMBER 16.

21932. **Improvements in electric cigar-lighters and analogous objects** Friedrich Wilhelm Schindler, 433, Strand, London

21933. **Improvements in electrical cooking appliances.** Friedrich Wilhelm Schindler, 433, Strand, London.

21958. **Improvements in and relating to electric lamps for bicycles and similar vehicles.** Henry Harris Lake, 45, Southampton buildings, Chancery lane London (George Mayr, United States)

NOVEMBER 17

21966. **An improved electrical drop indicator.** Ebenezer Beal, 167, Highfield road, Seeley, Manchester.

22027. **Improvements in electric instrument protectors** Henry Reason, 111, Gloster road Brighton

22030. **A method of applying electricity to the mechanism of lights for lighthouses buoys beacons, and the like.** Henri Marie Hubert, Comte Delamarre 28, Southampton buildings, Chancery lane, London

22032. **Improvements in accumulator batteries** Georges Rene Blot, 28 Southampton buildings, Chancery lane, London.

22053. **Improvements in or connected with so-called "dry" electrolytes for secondary batteries.** Villeroy Corney Doubleday, 77, Chancery lane, London. (Max S. ...mann, Germany.)

NOVEMBER 18.

22075. **Improvements in electric furnaces for welding or heating metals** Charles Frederick Parkinson and the Lancaster Railway Carriage and Waggon Company, Limited, 6, Bank street, Manchester.

22089. **Compound plates for etching purposes, consisting of zinc electrically plated with copper or the like.** Hermann Bernert, 38, Alexander-strasse, Berlin.

22131. **Improvements in switches for controlling electric current circuits in parallel supply systems** William Lowrie, 433, Strand, London. (Complete specification.)

SPECIFICATIONS PUBLISHED

1892.

9347. **Electrolytic decomposition of halogen compounds.** Kellner (Second edition)

9799. **Electrolysis of alkaline chlorides** FitzGerald. (Second edition.)

19393. **Electric battery apparatus** Froggatt.

19720. **Rectifying alternating currents.** Pollak.

19959. **Measuring electricity.** Humphreys and Friese Greene

20598. **Electric accumulators.** Therye and Oblasser.

20610. **Telephone circuits** Anders and Kottgen.

21602 **Electric meters.** Scott.

22539. **Dynamo electric machinery.** Spence and others.

23075. **Electric switches.** Raworth.

23392 **Telephony** Hutin and Leblanc

1893

516 **Measuring and recording electric currents** Lake. (Weston.)

17646 **Telephone switch.** Ness

18170. **Electrical contacts.** Raworth.

NOTES.

Fire Alarms.—A new type of fire alarm has been devised by a member of the Cardiff police force.

Queen's Hall.—This hall, situated in the West-end and opened the other day, is lighted throughout by electricity.

Shipley.—The Local Board have decided to apply to the Board of Trade for sanction to borrow money to acquire the tramways.

Scientific Toys.—Mr. James Swinburne discoursed to an audience at Victoria Hall last week on the scientific aspect of penny street toys.

The Brighton-Rottingdean Railway.—The share list of the Brighton and Rottingdean Seashore Electric Tramroad Company was closed yesterday.

Accident.—On Saturday, whilst William Musgrave was attending to the electric light plant at West Hartlepool, he was caught by the machinery and killed.

Book Received.—We have received for review copy of "Helical Gears: A Practical Treatise," by "A Foreman Patternmaker," and published by Messrs. Whittaker and Co.

Supply and Measurement.—Prof. Silvanus P. Thompson, F.R.S., has delivered a lecture at the Victoria Rooms, Bristol, on the "Supply and Measurement of Electricity."

Obituary.—The death is announced of Mr. Joseph Heywood, who was for 41 years lecture-assistant and steward of the chemical laboratories at Owens College, Manchester.

Personal.—We are informed that *Industries and Iron* has lost the services of Mr. James Swinburne as electrical editor, but that this gentleman will remain a contributor to that journal.

Foremen Engineers.—The annual dinner of the Newcastle and District Association of Foremen Engineers and Mechanical Draughtsmen has been held in the County Hotel, Newcastle.

"Not an Injun."—One of the speakers during the discussion at the Institution last week declared that, as he was not a wild Indian, he would not call Niagara, "Nee-à-gahrra," but Ni-ag-ara.

Lightship Communication.—Telephonic communication between the Gunfleet lightship and the coastguard stations at Harwich, Walton-on the-Naze, and Clacton-on-Sea has been completed.

The Azores Cable.—The Eastern Telegraph Company announce that telegraphic communication has been established between the company's station at Lisbon and the Island of Graciosa, in the Azores.

The New Mauritius Cable.—The new cable connecting Mauritius and the Seychelles with Zanzibar, and thus with Europe, was inaugurated on the 25th ult. by the governor, Sir Hubert Jerningham.

City Lighting.—A correspondent asks in a City paper for an explanation of the cause of the extinction on Friday last, for 20 minutes, of the incandescent lamps used in private installations in Moorgate-street.

Society of Engineers.—The next ordinary meeting of this society will be held at the Town Hall, Westminster, on Monday. A paper will be read on "Some Practical Examples of Blasting," by Mr. Perry F. Nursey.

"Don't Read This."—"Do you know," asked *l'homme terrible* (not *l'enfant terrible* this time) as he entered our office the other day, "why are lamp trimmers are so courteous? "No," was the response. "Because," he replied, "they are po-lite men."

Transmission of Power.—Several new schemes are under consideration for the electrical transmission of power from distant parts to Milan. The Societa Italiana per le Condotte d'Acqua is now transmitting 1,000 h.p. from Tivoli to Milan.

Power Station v. Central Station.—The general term of "central station" is rather ambiguous. Prof. S. Thompson suggests that "power station," as adopted by Prof. Forbes in his paper concerning Niagara, is decidedly better, the words "central station" being rather misleading.

Society of Arts.—On Monday, at 8 p.m., the second Cantor lecture on "The Art of Book and Newspaper Illustration," by Mr. Henry Blackburn, will be delivered. On Wednesday, at 8 p.m., a paper will be read by Mr. Frederic Villiers on "An Artist's View of Chicago and the World's Fair."

Industrial Applications of Electricity.—The course of public lectures which are given annually at the Conservatoire des Arts et Metiers in Paris has just commenced for the current year. M. Marcel Deprez lectures every Monday and Thursday on the industrial applications of electricity.

The Decimal System.—The Leeds Chamber of Commerce have resolved, in view of the expected discussion at the coming conference in London, to recommend the adoption of a metrical system of weights and measures, and that the pound sterling should be taken as the unit.

Students of the Institution.—A meeting of the students of the Institution of Electrical Engineers will be held this (Friday) evening at 28, Victoria-street, Westminster. A paper on the following will be read: "The Mechanical Testing of Electro-Deposited Films of Metal," by Mr. Arnold Phillip.

Dynamo-Electric Machines.—The second edition in French of Prof. S. P. Thompson's book, "Traité Theorique et Pratique des Machines Dynamo-Electriques," has just been issued by Messrs. Baudry and Co., 15, Rue des Saints-Pères, Paris. The work has been translated and adapted from the fourth English edition.

Colliery Managers.—A meeting of the Association of Colliery Managers took place on Saturday in Edinburgh, the president, Mr. William Roy, Holytown, in the chair. The discussion on Mr. Weir's paper on "The Application of Electricity to the Development of Dip Workings and other Purposes," was resumed and closed."

Traction at Croydon.—An important movement has been started by the Corporation, who are seeking powers to construct tramways in the borough to be worked by animal or mechanical power. The Corporation have had facilities for judging the advantages of mechanical traction, and electrical engineers should take a "stitch in time."

The Institution.—The annual general meeting will be held at 25, Great George-street, Westminster, S.W., on Thursday, the 14th inst. The annual report of the Council will be presented, and the election of Council and officers for the year 1894 will take place. "The Electrical Transmission of Power from Niagara Falls" will be further discussed.

The Stopping of Trolley Cars.—A Rochester (U.S.) man has devised a plan by which a trolley street car can be stopped almost instantaneously, or within a space of 3ft., while the car is going at full speed. As he omits,

however, adds the *Railway Review*, of Chicago, to provide for stopping the passengers, it is only fair to presume they will object.

Elieson Company v. The Earl of Galloway.—With reference to this case, which was reported in our last issue, Mr. Watson Smith, editor of the *Journal of the Society of Chemical Industry*, writes that he is not the person bearing the name of "Watson Smith" who figured in that case, and that they are not connected by any bond of relationship.

Private Bill Legislation.—The time for giving notice in the *London Gazette* of all English and Welsh Private Bill legislation for next session expired on Tuesday, when notice had been given of 154 Bills. Two of these Bills are promoted by the Central London Railway Company, and the Charing Cross and Hampstead Electric Railway Company.

Royal Institution.—The annual course of lectures for children will this Christmas be delivered by Prof. James Dewar, F.R.S. The subject will be "Air—Gaseous and Liquid," and the first lecture will be delivered in the theatre of the Royal Institution on Thursday, December 28. The next general monthly meeting of the members will take place on Monday next.

The Attack on Gas.—The agitation in North London against the high price charged for gas is still proceeding. Mr. J. Rowlands, M.P., who delivered an address on the subject on Tuesday evening, said that the electric light would soon become more used, and then the gas companies would be at a discount. Hammer away, ye Finsburyites, but go in for electricity.

Exhibition of Inventions. — An international exhibition of inventions, under the auspices of the Society of Industry of Copenhagen, which is to be opened on the 5th January next, will consist of models and specimens and illustrations of inventions of interest to Scandinavia. Messrs. W. P. Thompson and Co., 6, Lord-street, Liverpool, have the matter in hand.

Steering Balloons.—In connection with the revolution proceeding in Brazil, it is stated that a great balloon has been constructed for operation against the insurgent fleet, and that a quantity of bombs has been prepared for its special use. The balloon is said to be equipped with an electric motor, which, it is stated, will steer the balloon perfectly. We have heard of this before, and shall no doubt again.

"Venus" Incandescent Lamps.—We note that Mr. G. Straus, who has occupied temporary offices at 158, Strand, W.C., has now removed to more commodious offices at 130, Queen Victoria-street, E.C., where he has on view a large assortment of "Venus" incandescent lamps. It is claimed for the "Venus" lamp that its life and efficiency are unsurpassed, whilst at the same time the prices are low.

Traction at Morecambe.—The chairman of the Morecambe Tramways Company, in reply to a question put on Wednesday by a shareholder, as to the advisability of adopting electricity as the motive power, replied that at present this was impracticable, the local authorities objecting to the overhead system, and the cost of carrying and charging accumulators being at the present time less economical than horse traction.

Lights in Loch Fyne.—In answer to Mr. Macfarlane, Mr. Mundella remarked in the House of Commons a few days ago that the Board of Trade have no power of initiation in the establishment of lights, and that their duty is confined to sanctioning or refusing applications submitted to them by the general lighthouse authorities. The Commissioners of Northern Lighthouses have at present some large and costly works in hand.

The "Medical Battery" Company, Limited.—The further hearing of the charge of fraudulent conspiracy brought against Cornelius Bennett Harness, managing director of the "Medical Battery" Company, Limited, James M. McCully, C. B. Hollier, and W. R. Sellman (otherwise Dudley Towers) was resumed by Mr. Hannay at the Marlborough-street Police Court on Wednesday and yesterday. The case was again adjourned until to-day (Friday).

Telegraphic Addresses.—Mr. Henry Sell, in reference to his projected "Directory of Registered Telegraphic Addresses," states that he has now received the whole of the lists from the Post Office. The reply to the Postmaster-General's query as to whether firms would consent to his giving him their various registered telegraphic addresses has been all but unanimous in favour of the publicity, the number objecting being only a few hundreds out of some 45,000 persons or firms applied to.

Earthquakes and Cables.—On Monday, at the London Institution, the Rev. H. A. Boys delivered a lecture on the subject of earthquakes in the Grecian archipelago. The terrible earthquake on the south-west of the Morea in 1886 was felt at Zante. As an illustration of the crumbling effects produced, the lecturer remarked that the submarine cables from the island were snapped, and that when the engineers came to relay them it was found that the sea bottom was from 400ft. to 1,000ft. lower than before.

Lighting Mail Cars.—The German Postal Department has recently been testing the practicability of lighting mail cars with incandescent lights instead of with gas. The current has been supplied by storage batteries of a capacity sufficient to keep eight lamps of 12 c.p., each burning brilliantly and steadily, at a cost of ⅜d. a light per hour, against an expense of ½d. a light per hour when gas was used. Thus the electric light seems to offer advantages from an economical as well as a hygienic point of view.

Rectified Currents.—The Société d'Eclairage et de Force at Paris have granted a license for the Leblanc-Hutin patents to the firm of MM. Farcot. The latter will at once commence the manufacture of apparatus of large powers for rectifying alternate currents. In this connection it is interesting to note that in the electric light works which are on the point of being started at Saint-Ouen Epinay, it is intended to use alternate current produced at Saint-Ouen for the charging of accumulators at Epinay by the use of a rectifier.

Power Transmission to Macerata.—This Italian town is now lighted by electricity, the current being transmitted a distance of four miles. Water power is used, there being two Escher-Wyss turbines coupled by means of Raffard couplings to two Oerlikon dynamos giving current at 2,400 volts. The conductors are carried overhead, and the loss on the line is 300 volts, the pressure of the current on reaching Macerata being 2,100 volts. A portion of the current is used for public incandescent lighting in series, and the remainder is distributed on the three-wire system.

Seismology.—Hitherto, the prime difficulty of seismologists has been to ascertain the exact time at which an earthquake shock strikes a given locality, the data being, even within an area of not many yards, often very vague. To obviate this inaccuracy, we gather from *L'Elettricista*, as quoted in *Nature*, that Dr. A. Cancani, of the Rocca di Papa Observatory, has devised an ingenious electrical instrument. This, it appears, consists of a chronometer, the face of which is photographed by "the light of an

incandescent lamp, lighted for about a quarter of a second by a current established automatically by the shock."

The Antwerp Exhibition.—Arrangements are now in progress for the adequate representation of Great Britain and Ireland at the forthcoming international exhibition at Antwerp, which is to be opened in May next. The exhibition includes industrial, scientific, and artistic productions, maritime, Colonial and African sections, etc. The scheme has received the approval of the London Chamber of Commerce and the Associated Chambers, and a programme indicating their co-operation will shortly be issued. Meanwhile, information will be supplied in London by the Chamber of Commerce.

Traction at Leeds.—The Highways Committee of the City Council, on Wednesday, considered the subject of applying electricity as a motive power on the tramways. This undertaking is shortly to come into the possession by purchase of the Corporation, and it is thought that opportunity might be taken of the change to introduce electricity instead of horse and steam power. Mr. R. Hammond attended the committee meeting, and conferred with the members as to the different systems in operation throughout England and other countries. He described the conduit system in use in Budapest, and replied to numerous questions put to him by members regarding the working of the overhead wire system.

"Standard Tables for Electric Wiremen."—A copy of the fourth edition of "Standard Tables for Electric Wiremen," by Mr. C. M. Davis, has been forwarded to us by the W. J. Johnston Company, Limited, of 167-176, Times-building, New York. In addition to giving standard tables for wiremen, the booklet contains instructions for wiremen and linesmen, useful formulæ and data, and the latest revisions of the insurance rules of the Underwriters' International Electric Association. The wiring tables are according to the Brown and Sharpe gauge, and this, combined with the fact that the costs are given in American money, renders the book of greater value to those in the United States than to those in the United Kingdom.

The Central London Railway.—As mentioned in our last issue, a Bill will be introduced into Parliament next session to extend the time within which to construct the Central London Railway (authorised in 1891) from Shepherd's Bush, under Uxbridge-road, Oxford-street, High Holborn, Cheapside, to the Mansion House, and subsequently extended in 1892 as far as Liverpool-street Station. The time for taking the land required will, if not extended, expire next year. It is understood that the Bill will also contain clauses for the purpose of relieving the company from the payment of compensation for the subsoil through which the railway will pass, which was a right conceded to landowners, after great opposition on the part of the company, by a committee of the House of Commons. The company do not intend, as some papers have erroneously stated, to work the line by some power other than by electricity.

A New Police-Signal System.—A demonstration of Davis's improved signal system took place last week in Liverpool. The invention is that of Mr. Edward Davis, an Englishman resident for some years in America, and who there gained experience under some of the best firms. Through the medium of a metal box fixed at any point throughout the city a system of communication with the head office can be established. By means of a key, with which the policeman or watchman is entrusted, he opens the box, and should he want to bespeak the services of a patrol waggon or ambulance, or raise an alarm of fire, he has only to press a particular knob and the telegraph wire connecting the box with the head office instantly transmits the message to its destination. Not only does it do this, but it is said to automatically record on paper the time at which the signal was received, the number of the key by which the box was opened, and that of the box itself, thereby successfully individualising the policeman making the signal or sending the message.

Regulating Clocks by Electricity.—In our issue of the 6th October reference was made to an improved system of regulating clocks by electricity. A demonstration of the method was given last week by the Standard Electrical Time-Recording Company, Limited, at 39, Victoria-street. By this system time-recorders to any number can be governed by a self-contained installation, and every station clock upon a railway system can be controlled, or a few clocks in a country house can be kept uniformly correct by a simple battery. The receivers are placed in circuit with the regulator clocks. The contact is of short duration, being only one-eighth of a second, but the working of all the receivers within the circuit is said to be perfect and their synchronisation absolute. By a special arrangement, the movement of the hands of all the receivers takes place before the complete break of the current in the regulator. The contact is made in the regulator clock every half-minute, the current winding up the main spring simultaneously. From a single regulator clock any number of receiver dials can be worked.

The French Cable Subsidy.—Now that New South Wales and Queensland are being twitted all round with their action in subsidising the first section of the French cable from Queensland to Canada, says the *Pall Mall Gazette*, they try to excuse themselves by declaring that they are committed to nothing beyond supporting the first section of the cable from Australia to New Caledonia. This contention is in no sense borne out by the official documents which embody the exacts terms of the arrangement between the colonies and the cable company. As the Sydney *Daily Telegraph* puts it: "We (New South Wales) are not only saddled with Queensland in a joint guarantee for a period of 30 years, but have been made to agree that this French cable 'shall form part of the main Pacific cable connecting Queensland with Vancouver, San Francisco, or other places in North America as may hereafter be determined!'" Language could not be more definite than this, and the engagements entered into by New South Wales and Queensland will obviously, in spite of their optimistic disclaimers, seriously hamper them in affording assistance to an all-British cable should its construction be decided on, as the result of Mr. Sandford Fleming's visit to Australia.

The Halifax Fire. We stated last week that on the 23rd Nov. a serious fire occurred at the electrical engineering works in Square-road, Halifax. The building was five storeys high. The two upper storeys were tenanted by the Northern Electric Wire and Cable Company, Limited, and there were in these rooms many valuable machines, besides large quantities of wire. The two floors next below were formerly tenanted by Messrs. Blakey, Emmott, and Co., Limited, electrical engineers. A few weeks ago their plant was sold by auction, and the rooms have since been empty. On the first floor Mr. Walter Emmott, electrical engineer, had his business, and his stock comprised lathes, electrical machines, etc. In the cellar the Mutual Electric Light Company, Limited, had their plant for supplying electricity to shops in the town. This plant included five large dynamos and three engines, the whole having been put down at a cost of £3,000. The fire broke out shortly after midnight, and the building was soon burned down. A rough estimate of the damage is £10,000

or £11,000, which is all covered by insurance. The Electric Wire Company are insured in the Royal Exchange and Lancashire Companies, while Mr. Walter Emmott is insured in the Kent Insurance Company. The Electric Supply Company have their plant fully insured in the Scotch Alliance Company. As a result of the fire, the Mutual Electric Light Company are unable to supply light, and tradesmen who had been dependent on this source have been obliged to resort to other means for illuminating their premises.

Electric Lighting in the City.—Colonel Haywood, the engineer and surveyor to the City Commission of Sewers, has recently submitted a report, to which reference was made in a previous issue, showing the failures of the public electric lighting in the City which occurred during the half-year ending October 31, and the occasions on which gas has been used in substitution. He states that the returns of these failures were made by the police. The total number of arc lamps in use up to the present time is 479. The number of gas lamps disused but maintained ready for lighting is 1,219. The total number of failures of the electric lamps during the half-year was 301, each lamp being counted separately nightly. The most serious failure happened on May 7, when 42 electric lamps were not lighted for periods varying from one hour 30 minutes to two hours 34 minutes. On that occasion the gas lamps were lighted. The excuse was a defective switch, the fault in which was not discovered earlier in the day. The majority of the other failures, however, were not in groups or for long periods of time, and if the total number of hours the lamps failed were divided into the total number of hours that the whole of the electric lights were burning during the six months, the percentage of time when the lamps failed was but small. The 479 arc lamps in use nightly cost each £26 per annum, or £12,454 in all. The length of street in which arc lamps are fixed is about 13 miles. The 1,219 gas lamps which are maintained ready for lighting, cost annually about £1,182. The fines for these defects in lighting, as prescribed by the contract with the Commission, has been deducted from the accounts of the electric lighting company.

A Large Mine Pump.—The most striking piece of machinery in the mining exhibit of the General Electric Company at the recent Chicago Exhibition, was a single-reduction electric pump employed to furnish a head of water to a Pelton wheel in the exhibit illustrating the transmission of power by three-phase currents. This pump is triplex double acting, having outside packed plungers, operated by means of cross-heads and connecting-rods, from an extra heavy forged steel crankshaft. It was designed for mine work, and has a capacity of 500 gallons per minute against 650ft. head. The plungers are of bronze, have a diameter of 5⅝in., and are 18in. stroke, and when operating at full capacity require 50 revolutions of the crankshaft per minute, giving a plunger speed of 150ft. The cylinders and valve-chambers are made of composition metal in order to resist the action of bad mine-water. The pump is operated through a single set of gears by a six-pole 75-kilowatt motor, making 275 revolutions per minute. This necessitates a reduction of only five to one at the gears. The design of the pump is, in many respects, novel. The arrangement of the armature shaft, which is prolonged over the top of the pump, brings the motor to one side of the pump instead of in front, as is usually the case. By this means a great saving in space is effected, and this fact is a matter of considerable importance when it is a question of installing pumps in the underground recesses of mines. The pump throughout is solidly, substantially, and extra heavily constructed, and may be run for long periods without cessation at its full rated capacity. An electric pump of similar capacity to this has been for some time past operating successfully in the Calumet and Hecla mine.

Old Students' Association.—The report for the session 1892-93 of the Old Students' Association of the City and Guilds of London Institute has been issued. The report states that during the year the following meetings were held: the annual dinner, a dance, two smoking concerts, addresses by the president (on "Human Dynamics") and by Mr. Clinton T. Dent (on "Mountaineering"), and papers by Messrs. Brew and Ledger ("Central-Station Notes") and Mr. Howard Swan ("The Series Systems of Learning Languages"). The association has sustained great losses during the session in the deaths of Mr. H. C. Saunders, Q.C., and of Mr. Anthony Reckenzaun. The committee are of opinion that, in order to attain a larger measure of success, the association should be so developed that its operations do not conflict with those of other bodies, and that in the future greater prominence should be given to the social aspects of the work. The committee suggest, therefore, that the association should be worked on more distinctly social lines, and that for this purpose meetings for the reading of scientific papers should only be held when matter arises of sufficient importance; that three regular meetings—viz., a dinner, a conversazione, and a smoking concert—be held in each session; and that the subscription be made a nominal one. The committee state that the thanks of the association are due to Mr. Clinton T. Dent and Mr. T. E. Gatehouse for their assistance at the meetings, to those members who have read papers or otherwise helped during the session, and to the authorities at the Central Institution and Finsbury Technical College for the use of the rooms. A general meeting will be held on Tuesday next at 8 p.m. at the Finsbury Technical College, to receive the annual report and balance-sheet and to consider the scheme proposed for the future working of the O.S.A. Mr. Ll. B. Atkinson, the retiring president, will give an address, entitled "A Trip to Chicago."

Technical Education.—On Monday, Lord Derby distributed, at the Crewe Mechanics' Institution, the prizes and certificates awarded upon the results of examinations by the Victoria University, the Science and Art Department, the Union of Lancashire and Cheshire Institutes, the City and Guilds of London Institute, and the Society of Arts. In the course of an address, the Earl of Derby said there were now in science many openings, and many chances were placed in the way of those who desired to apply themselves practically to science, of acquiring that information and teaching upon which alone in these days scientific progress rested. As an instance, he mentioned that it was in comparatively recent years that magnetism and electricity had become subjects of practical study, or formed a part of our daily life. Now there was hardly a square mile of the country which did not owe something to telegraphy. There was not a square yard of the great railway system with which Crewe was connected that could be worked under present conditions without the aid of electricity. Many persons believed, as he did, that we were only at the opening of the dawn of greater progress in that respect. The application of electricity to the transmission of power and its diffusion in small motors were matters which affected our everyday affairs, both in the manufacture and conduct of machinery and in regard to those questions which were pressing themselves to the front nowadays. For his own part he believed that those who now would take up the study of electricity would have hereafter brought before them probably some of the most complex and at the same time the most interesting problems to solve that were to be found in any other branch of science. They had yet

very much to learn, and there were great openings in the future for those of quick brains and ready hands in the department of practical science. It might not be given to everybody in that room to achieve such triumphs in mechanical construction as his friend, Mr. Webb, or his predecessor, Mr. Ramsbottom, won, but still there were many persons in the audience who would yet make their mark and find success by persevering industry, by their skill in science, and by the knowledge which they had gained at that institution.

The Liege-Herstal Electric Tramway.—Some time ago we referred to the opening to traffic of the electric tramway between Liège and Herstal in Belgium, and we now give from *L'Electricien* of the 25th November some particulars concerning this line. The system adopted is the overhead trolley method, the return being formed by the rails and the earth. The generating station contains two multitubular boilers of the de Naeyer type capable of working up to 120lb. pressure, and provided with feed-water heaters and Worthington pumps. The steam is supplied to two engines, each of 60 h.p., running at 130 revolutions a minute. These engines are provided with variable regulators, and have been made by the Société Anonyme "le Phenix" of Ghent. Each engine drives a four-pole dynamo giving 100 amperes at 550 volts when driven at 700 revolutions, and made by the Allgemeine Elektricitäts Gesellschaft of Berlin. The total length of the line, which is single throughout, and provided with three loops for crossings and switches at each terminus, is nearly two miles, and it is of 4ft. gauge. The line has some steep gradients and stiff curves. The rails, which weigh 63lbs. to the yard, are laid on metallic sleepers with the interposition of ballast. As far as the electrical connections between the rails are concerned, two galvanised iron wires, 6mm. diameter, are connected to the rails at intervals of 7ft. by means of pins inserted through the sleepers and the rail. Not content with this arrangement, eight earth-plates have been placed in pits at a depth of 65ft. in the ground. The object of these plates is to equalise the potential of the rail with that of the earth, and to confine any leakage to the lower parts of the soil instead of permitting leakage in the upper part, and therefore into the telephonic system, etc. Notwithstanding these precautions taken to eliminate any disturbing effects in telephone working, troubles have arisen which have attracted the attention of the telegraph and telephone service. A good earth constitutes an excellent condition for the working of a tramway, but the efficacy and the excellence of the methods applied to ensure the return of the current through the earth do not exempt the system from inconveniences inherent to its own constitution. The phenomena observed at Liège furnish another proof of this fact. The overhead conductor is carried on iron standards erected at intervals averaging 108ft.; these standards also support two feeders, one of which is carried one-quarter of the length of the tramway, and the other the remaining three-quarters. These feeders are respectively of 35 square millimetres in section, and 150 mm. The trolley wire is of Montefiore phosphor bronze 7mm. in diameter; it is carried partly on brackets attached to the poles, and is partly supported by steel transverse wires. With regard to the rolling-stock, constructed by the Société Saint-Léonard, of Liège, only one motor is fitted to each car. This type of motor, made by the Compagnie Internationale d'Electricité, of Liège, is of 25 h.p. The armature shaft is prolonged, the prolongation being provided with a pinion gearing into a toothed wheel arranged on the car axle. The speed of the motor is regulated by means of a rheostat connected with two contact squares, upon which pass two brushes in connection with the brushes of the motor. The initiative in this enterprise was taken by the Société des Tramways Liègeois and the Compagnie Internationale d'Electricité.

The Dangerous Working Heat of Mild Steel.—A paper was read last week by Mr. J. Nodder before the North East Coast Institution of Engineers and Shipbuilders on "The Dangerous Working Heat of Mild Steel, and the Effect of Annealing and Air Cooling." The author pointed out that the more general use of Siemens-Martin steel for boiler purposes was perhaps limited by 15 years. The most reliable and satisfactory results from Siemens-Martin mild steel were obtained from material of 26 to 30 tons tensile, and not less than 20 per cent. elongation in 8in., the distinction between high and low tensiles within this limit being a fallacy. Steel of 26 tons tensile or 30 tons tensile could be produced from the same ingot almost at the will of the plate-roller, certainly without any variation of the chemical constituents of the material, and the same failures would be produced by mechanical treatment in steel plates anywhere from 24 tons tensile strain to the square inch to 30 tons per square inch. Basic and Bessemer steels were subject to the same weaknesses, though Bessemer steel developed faults in working out of a fire that made it unsuitable for general boiler work, and its use was very limited. Basic steel, if made on the open-hearth system, gave very similar results to Siemens-Martin steel; but practical experience has not yet developed sufficient confidence in its use as a substitute for Siemens steel in external and internal flanged boiler work. An increased elongation, say, to 25 per cent. in 8in. of steel 30 tons tensile would show greater ductility than 24 tons tensile with only 20 per cent. elongation. This was a point that is generally overlooked, a demand being made for a lower tensile rather than an increased elongation. Similarly, much was made of a "flanging test," but the only reliable test of steel was that obtained by the actual measurement of the force applied and represented by the tons tensile and the percentage of elongation. Bending tests—cold, hot, and quenched—were useful aids, the latter especially, but unless the force used for bending was accurately measured the test could not be tabulated, and was only of service in conjunction with the tensile tests. After referring to tests made years ago, the author stated that experiments conducted at Messrs. John Brown and Co.'s works in 1892 and 1893 would place the dangerous heat near 400deg.; that Siemens or basic steel hammered at that temperature retained all the brittleness resulting from that dangerous heat, even when cold, which did not appear in experiments made in 1881; and that reheating without "work" would restore all the ductility that previously existed. The results of a long series of tests would teach that the heating and reheating of Siemens steel made little or no difference to the structure of the material when cold, providing no work had been put upon it between 400deg. and 600deg., and also that steel might be hammered and bent cold without detriment. Annealing was another of the vexed questions that surrounded steel, and the effect of air cooling had been the basis of much theorising upon the causes of failed furnaces, tube plates, etc. The result of experiments to which he referred proved that air cooling, even under extreme variations of temperature, could make no appreciable difference to this class of material. The same could not be said of water cooling, and a comparison of tests showed a marked change, and an increase of 10 tons per square inch tensile, and a decrease of 51¾ per cent. of elongation, after heating to 1,500deg. and cooling in water at a temperature of 60deg., making the material quite unfit for service without again reheating.

F. J. DOWN.

Mr. F. J. Down, F.C.S., M.I.E.E., was born at Bristol, Somersetshire, and educated at Macclesfield, Sandycroft College, and Wiesbaden. From Sandycroft College, Mr. Down went to Glasgow, and became apprenticed to Messrs. A. and W. Smith, of Cook street, general engineers and boiler makers. After his time was out he went over to Wiesbaden, and there studied physics, chemistry, etc., under Prof. Newbauer at the celebrated laboratory of Prof. Fresenius. On his return to England he at once entered the chemical works belonging to Messrs. Charles Tennant and Co., chemical manufacturers, at Hebburn-on-Tyne, where he remained about five years, and afterwards left there to carry out, on behalf of the Blaydon Chemical Company, first in the laboratory and afterwards on a commercial scale, various new processes being there introduced. From there he came to London, and at the works of the Silicate Paint Company, of Charlton, Kent, introduced the manufacture on a large scale of sulphide of barium, which is principally used for the making of their non-poisonous paints. Being desirous of entering into business in London, through mutual friends he joined Messrs. Laing and Wharton, the accredited agents of the original Swan Company, on Holborn-viaduct, the name of the firm becoming Laing, Wharton, and Down, who, as electric light engineers and contractors, have already successfully carried out a very large number of electric light and power installations. This firm brought from America the Thomson-Houston system of electric lighting, now so largely used by railway companies, central stations, and recently chosen for the large central station for the lighting of the eastern division of the city of London. This system was first introduced into England at the Inventions Exhibition in 1885, where it created great interest, and was exclusively employed in lighting the American Exhibition in 1887, the Italian Exhibition in 1888, and the great Military Exhibition in 1890. Mr. Down has always been a most energetic member of the firm, and has won a wide circle of friends in the industry into which he has thrown his lot.

SOME RECENT DEVELOPMENTS IN ALTERNATING-CURRENT MOTORS.

BY ELIAS E. RIES AND GORDON J. SCOTT.

Among the most interesting and valuable features that characterised the work of the International Electrical Congress recently held in connection with the World's Fair at Chicago, were the remarks made by many of the distinguished delegates present upon the subject of the transmission of alternating currents and the respective merits of single and multiphase motors for power distribution. Although opinions were somewhat divided upon this latter question, it was clearly recognised that the multiphase systems at present available were merely an expedient rendered necessary by the existing state of the art, and that the advent of a simple and efficient self starting single-phase alternating-current motor would at once establish the latter as the standard type for nearly all classes of electrical power distribution.

In the course of some extended experiments made by us upon the subject recently we have discovered and practically demonstrated a number of important facts, which in many respects revolutionise the theories that electricians have heretofore held and have been accustomed to regard as essential principles in the design and construction of alternating current motors. These discoveries, which promise to inaugurate a new departure in alternating motor construction, have shown us that it is not only possible to construct self-starting, non-synchronous, alternating-current motors of any desired power that will run economically on single-phase circuits of any commercial frequency—such, for example, as that in common use for incandescent lighting—but that such motors will be, everything considered, far more efficient, both electrically and mechanically, than the best continuous-current motors yet produced.

The difficulties hitherto encountered in attempts to construct self-starting variable-speed motors intended for operation on ordinary alternating current incandescent lighting circuits, have apparently been of an insurmountable nature. With the exception of the smaller types of motors developing a fraction of a horse power—such as those used for operating small ventilating fans, where economy in the use of current has been considered of minor importance, and in which the self induction in the energising coils and the losses in the magnetic circuit could be kept reasonably small—all attempts to produce efficient motors to operate on a simple two-wire alternating circuit, without the employment of more or less complicated auxiliary starting or lag-changing devices, have thus far failed. Even two-phase and polyphase motors as at present constructed, although self-starting under light loads, require for their efficient operation not only a low frequency that unnecessarily increases the size of the generating, transforming, and motor apparatus, and which renders it in many cases unsuitable for lighting purposes (to say nothing of the greater complexity of the feeding and distributing mains which such a system involves), but owing to the great sacrifice in electrical and mechanical efficiency when their normal speed is departed from, such motors cannot compete with direct-current motors for work where a variable speed with maximum torque is requisite—as, for example, in the case of electric street railways.

Following up our researches in the alternating-motor field, and with the view of producing a motor of simple construction that could be operated on any of the commercial alternating-current circuits now in use with reasonable economy, we built a number of experimental motors of various types and sizes, embodying some of the results of our investigations. These motors have been thoroughly tested in the factory of the Ries Electric Specialty Company at Baltimore, Md., and the results obtained have been so successful that we are now making preparations to build alternating-current motors for commercial uses that in the matter of efficiency, simplicity, weight, adaptability, and general excellence of operation will compare favourably with, if indeed they do not in these respects surpass, all existing types of electric motors.

Believing that the remarkable results we have already obtained will be of general interest at this time, we have thought it advisable to present herewith a photograph of one of the single phase motors built and used by us in some of our experiments, together with such information concerning its operation as we are at liberty to disclose at present.

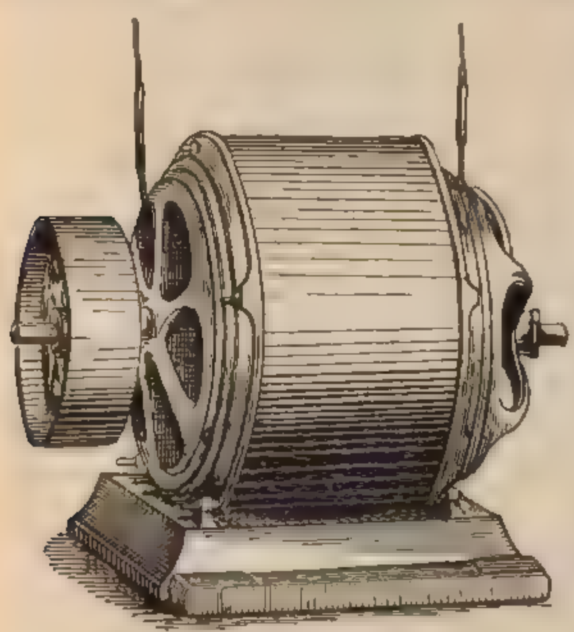
The motor illustrated has a capacity of 1 h.p., and was designed for and tested on an ordinary 50-volt alternating-current incandescent light circuit, having a frequency of 138 complete cycles per second. The most noticeable feature is its extremely small size and weight for a motor of its output and efficiency. The total height of this motor, including base, is 2½in.; the diameter of the motor proper, 9in.; the width of motor, exclusive of end plates containing bearings, 5in.; the total length of armature shaft, 11½in.; while the total weight is but 35lb., of which only 2lb. are copper.

Actual brake measurements were made upon this motor, while the same was running at various speeds, on an ordinary 50-volt incandescent circuit of 138 complete cycles per second. At a speed of 2,000 revolutions per minute, taking 15 amperes of current, the motor developed 26,400 foot pounds, or ·80 h.p., at an electrical efficiency of 90 per cent., the motor remaining perfectly cool after a continuous run of eight hours. With 10 amperes of current the power

developed was 17,850 foot-pounds, or ·54 h.p., with an electrical efficiency of 93 per cent.

On increasing the load on the motor, and thus reducing the speed to about 1,000 revolutions, with the same flow of current, the power developed was substantially the same as before, with very nearly the same efficiency. When the speed was reduced below 600 revolutions, however, the efficiency dropped appreciably, although not enough, even in the case of the present high-speed machine, to detract from its usefulness for continuous and effective work at speeds very much below those hitherto found practicable in direct-current work.

The diameter of the driving pulley is 5in., yet, notwithstanding this, the torque developed by the motor is so great that it starts off promptly under full load. The speed of the motor, as has been fully demonstrated by these tests, is variable within wide limits and without appreciable loss in efficiency—a result that has not heretofore been obtainable either with direct or alternating current motors. Another and most valuable characteristic of one type of the motor under consideration is that with a given flow of current the torque increases up to a certain point as the speed decreases. This peculiarity is likewise entirely new, and of the utmost importance, since it not only provides an exceedingly high starting torque, but enables the motor to develop its maximum power continuously at the highest



Ries and Scott 1-h.p. Single-phase Alternating-current Motor.

possible efficiency and irrespective of the speed at which it may run.

It will at once be apparent that these features render this type of motor particularly applicable for all stationary and railway work where widely-fluctuating loads are encountered, especially so because the principles underlying its construction are such that, unlike direct-current constant-potential motors, it cannot of itself receive more than its maximum normal current under any conditions of use, and thus cannot possibly be burned out or injured by an excessive overload, or by any of the other causes which have proven to be such prolific sources of trouble in the case of continuous-current motors.

Perhaps the most remarkable feature about this machine is the fact that the losses and other difficulties that have heretofore attended the use of comparatively high frequencies for alternating-current motor work, whether single-phase, two phase, or polyphase, have been practically eliminated. Indeed, were it not for this discovery, the results here recorded could never have been obtained. It is probably not too much to say that this achievement, to which we have successfully directed our strongest efforts, will contribute largely to the adoption of higher and more economical frequencies for alternating-current work than those at present in vogue, or, at least, to the maintenance of the highest of the standard periods now in commercial use on lighting circuits, thus deservedly checking the precipitate and ill-advised tendency which is at present more or less prevalent both abroad, where multiphase systems have for some time been extensively used, as well as in this country, to adopt as a standard for general use a current of such a low frequency as would involve not only much larger and more expensive generators, transformers, and motors, but which would prove unsatisfactory and uneconomical to the highest degree for nearly every purpose to which it can be applied.

Since high frequency in alternating-current apparatus is the equivalent to high speed in direct-current apparatus, in being the seat of the direct and counter E.M.F.'s developed, and since it is well known that by increasing the speed of a direct-current armature the output of the machine for a given amount of iron and copper is very much increased, it follows that the higher the frequency that can be used the better the result obtained from an alternating-current motor of a given size and weight. While there are serious mechanical limitations to higher armature speeds than those now in use, there are, so far as the motor is concerned, no longer any restrictions to the use of higher frequencies, since the self-induction and hysteresis, which in all previous types of alternating-current motors have been the principal sources of loss, are now for the first time utilised in our motor and turned to practical account, as shown by the fact that the motor runs perfectly true, despite the small quantity of iron and copper in the machine. Thus on circuits of higher frequency the alternating-current motor will possess not only an enormous advantage over its continuous-current brother, in the matter of safe and economical transmission over long distances of the power that gives it its vitality and scope, but will be far superior to it as a motor by reason of its more simple and compact form and the correspondingly increased amount of the power it is capable of generating per unit of weight under these conditions.

In addition to the experimental motor illustrated herewith, we have built other single-phase motors of larger sizes that are now doing successful work in the factory of the Ries Electric Specialty Company, where they can be seen in operation. Some of these motors are designed for synchronous working and run at a constant speed under varying loads. As in the case of the variable-speed motor, they are self-starting, and run rapidly up to synchronism without the use of a special starting coil or switch, and will automatically regain synchronism should their speed be temporarily reduced below it by reason of a heavy overload.

We are now able to predetermine the characteristics of our motors with as much accuracy as with direct-current machines, and, as already stated, we are rapidly completing the designs for a full line of these motors, ranging all the way from a small-size $\frac{1}{6}$-h.p. alternating-current fan motor to the largest motors that may be required for stationary work. We have now likewise in course of construction a single-phase high-frequency alternating-current railway motor of 40 h.p. capacity, which will have less than one-half the usual weight of direct-current motors, and will embody some novel features peculiar to itself that are likely to have an important bearing upon the future of the electric railway.

To those who have been accustomed to the behaviour of direct or continuous current motors, or to those who have regarded the continuous current as the only practicable and economical one for power purposes, the remarkable performance of this motor and the simple manner in which these results are obtained is little short of marvellous. The comparatively high frequency of the alternating current used, the adaptability of the motor to the ordinary single-phase circuits, the exceedingly small size and weight of the motors compared with direct-current machines of similar capacity, the absolute reliability of their operation, the extremely slight internal losses in the machine, to which their unusually high efficiency is largely due, and the great simplicity of their mechanical and electrical construction—in short, the radical departures made by us in the entire design of these motors, regarding which we hope soon to be able to publish full details, causes these motors to excel in every respect all that has yet been accomplished by the continuous-current motor, and far surpasses in its reality the most sanguine expectations of even the foremost advocates of the transmission of power by alternating currents.

THE USE OF STORAGE BATTERIES IN ELECTRIC GENERATING STATIONS FOR UTILISING AND REGULATING POWER.*

BY C. O. MAILLOUX.

The diffidence with which I entered upon the task of preparing a report on the above subject for this association is sufficiently proven by the fact that I made a couple of unsuccessful attempts to decline the honour. My excuses and objections, however, availed me little with Mr. Longstreet, your honoured chairman, who soon had me enlisted. He doubtless did not realise at the time, and I myself did not realise till some time afterward, what a difficult task he had allotted me, and when I state, with full conviction, as the result of my investigation, that probably no American engineer is competent to do this subject full justice unless he has been able to study it for several months in Europe, where alone the material for its study exists to any extent, Mr. Longstreet may agree with me that he should have selected for this report some European member of the association, if any there be.

From its title the present report may be construed to have for its object to discuss the question whether storage batteries are capable, and to what extent, of rendering practical service in electric generating stations, more especially those used for railway traction; and to bring before the association any facts or data relating to this application of storage batteries that may be of possible utility or assistance to tramway managers or engineers who have already or may have later, in consideration, the said application as an adjunct to a generating plant.

The question is not without some importance at the present time when power stations are multiplying and growing so fast as in this country, because this question is one that has an important bearing on the design of the station, since, if this use of storage batteries is really feasible and practicable, in the full commercial sense, its utilisation with a view to securing the full measure of its benefits and advantages would, in many cases, involve somewhat radical changes in the arrangement of the power station, and possibly even in the details of its operation. In Europe the use of storage batteries in central stations has unquestionably made great progress during the last three years, and has actually succeeded in commanding the respect, if not in entirely overcoming the scepticism, of electrical engineers generally. The irregularities of load on power circuits, especially for electric traction purposes, are the bane of the electric railway engineer; and they are too well known and understood to require further mention now, except to classify them; for in reality there are two kinds, which must be carefully distinguished from each other, almost as if they constituted distinct diseases, so to speak, requiring different treatment, even though they may appear together in the same case. We must, therefore, distinguish between "variations" and "fluctuations" of load. I would use the term variation to designate the effect caused on the station plant by putting on or taking off a certain number of cars, and the term fluctuation to designate those incessant and erratic ebbs and flows of current which are so familiar to us all, due to the starting and stopping of cars, changes of speed, grades, etc. The variations of load are defined as changes in mean or average rate of production for a given period of time; the fluctuations of load are defined as changes in rate of production from one instant to another. The distinction between the two will be more readily understood by reference to the accompanying load diagrams.

Fig. 1 shows the fluctuations in an electric tramway. Figs. 2 and 3 show the load curve in an incandescent lighting station.

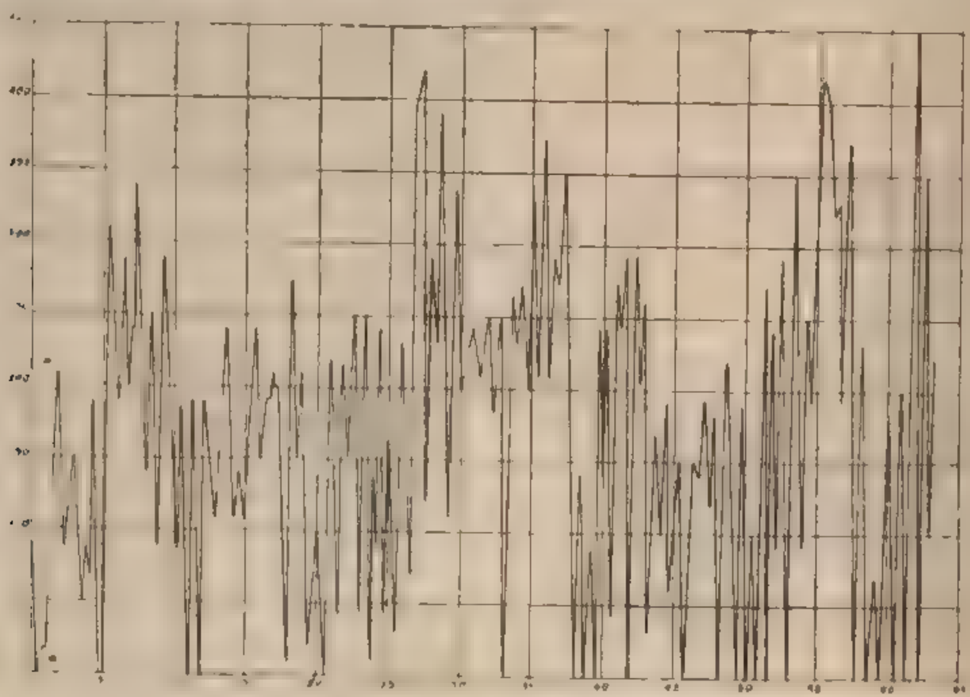


FIG. 1.

Taking the lighting station diagram in Fig. 3, which more nearly represents the usual condition of affairs in lighting stations, it is seen that the momentary irregularities (or fluctuations) are trivial in comparison with the changes (variations) of load from hour to hour, or from one part of the day to another. In the railway plant load diagram we observe a series of ups and downs following each other more or less irregularly every few minutes along the whole day. These seem like fluctuations as compared with the irregularities in Fig. 3. The term fluctuation should, in my opinion, include both the "waves" and the "sub-waves," while the term variation should be restricted to the "billows." It is proper to note that the waves and sub-waves above mentioned are relatively more numerous and marked in smaller than in larger railway power plants. The greater the number of motors supplied from a given source the less likelihood is there of the load being thrown on or off in such large proportions. The load then "averages itself," to use a current expression. Thus, where the number of motor cars represented is large (about 140), the load from 7 a.m. to 9 p.m. oscillates most of the time between 1,000 h.p. and 1,400 h.p., or 20 per cent. above and 15 per cent. below 1,170, which is the mean power rate for the whole day's run, excepting about 6 p.m., where a "wave" begins, lasting a couple of hours, during which the load reaches higher points, in some cases

* Abstract of a report presented to the Street Railway Association, America.

up to 1,750 h.p., or about 50 per cent. more than the mean power for the entire day's run.

Where the number of cars was less than 15, the load ranged at different times between 80 h.p., or about 50 per cent. below, to 380 h.p., or over 100 per cent. above the mean load (about 170 h.p.). The cases are numerous where the load falls down to zero, or runs up to two or three times the average load, in the course of a few minutes.

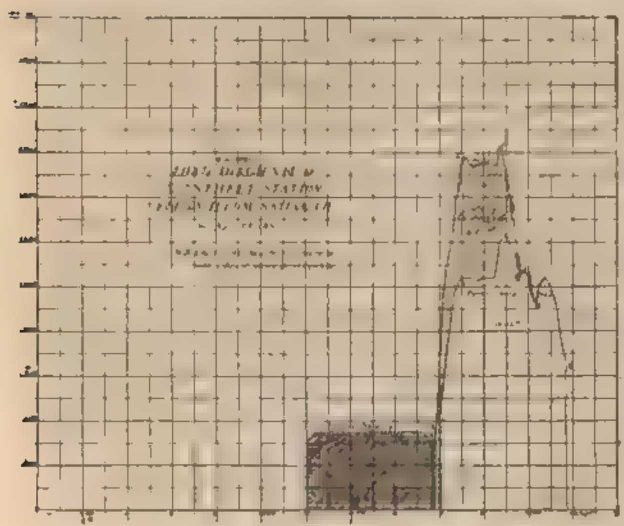

Fig. 2.

These fluctuations cost the railway companies money in three ways: First, because they involve the use of generating machinery of greater capacity than would be required if the machinery were operated at a constant uniform load; second, because the depreciation is greater; third, because the efficiency of the machinery is lower. The first two points are well understood. The third requires a slight analysis. The use of engines and dynamos greater than would be required for the mean load increases the percentage of energy spent in the engine and dynamo to overcome friction, and also to energise the field magnets as the friction load and magnetising energy (neglecting hysteresis and Foucault currents) must of necessity increase

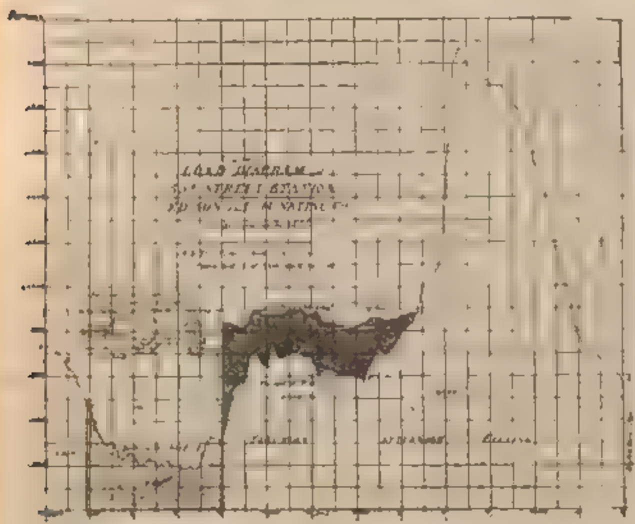

Fig. 3.

with the size of engine and dynamo. By courtesy of Mr. W. S. Barstow, superintendent of the Brooklyn (N.Y.) Edison Illuminating Company, I am enabled to publish (Fig. 4) two curves, A B, showing the percentage of the total indicated horse-power which can be obtained at the dynamo brushes under different loads. Curve A shows the performance of a vertical engine directly connected to a pair of multipolar (100-kilowatt) dynamos; while Curve B shows the performance of a high-speed engine belted to two Edison (70-kilowatt) generators; both engines being compounded and tested as nearly as possible under identical conditions. These curves show that by the time the load has fallen 40 per cent. the efficiency drops very rapidly.

Now, considering a little more closely the engine itself, several authorities have called attention to the extreme variations in steam consumption per indicated horse-power at various percentages of load, which is the real measure of the engine efficiency proper. Cases are not rare where the use of engines too large, but rendered necessary owing to the severe fluctuations to be compassed, have consumed from 10 to 15 per cent. more steam than they would at normal constant load. The total loss, of course, includes the loss in the engine cylinder as well as that due to mere friction. If the steam consumption is, say, 20 per cent. greater than it should be per average indicated horse-power, and if the engine and dynamo utilise 15 per cent. less of the indicated power than they would if of more suitable size and running under better conditions, the net efficiency will be the product of these two factors, or we might say in that case that only about seven-tenths of the steam is utilised. This means that if the same steam could be properly utilised it would do some 40 per cent. more work.

It is for the purpose of better utilising and economising this power that the storage battery is proposed to be used, by taking advantage of its property of being able to "give and take" energy, and thus keep the load balanced and equalised at all times. The principle of its action is that it can be made to absorb energy from the circuit (or the

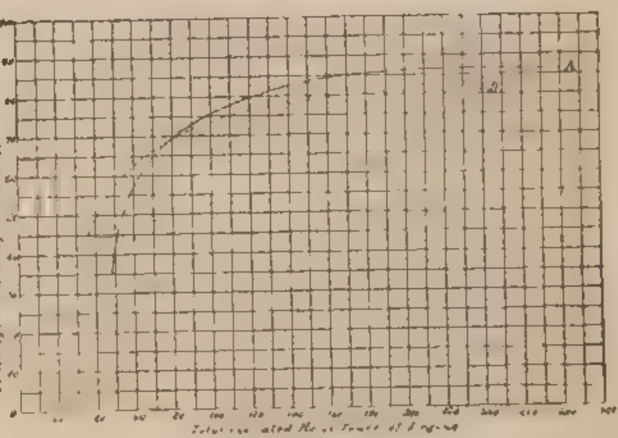

Fig. 4.

dynamos) or give it back in any desired amount, so that absolute control may be had of the total load imposed on the generating machinery independently of the rate at which the energy is consumed.

The use which has already been made of the storage battery for regulating the load in the central stations for electric lighting service is quite extended. It is thought that a brief reference to some of them will be of interest and utility.

By courtesy of R. R. Bowker, vice-president and manager of the Edison Illuminating Company, of New York, and with the kind assistance of William L. Pakenham, of the Crompton-Howell Electric Storage Company, Limited, of London, your committee is enabled to reproduce two interesting curves, showing the performance of a Crompton-Howell storage battery (140 cells, 51 plate elements) which is in use at the Edison Illuminating Company's Fifty-third-street station. This case is detailed first—although it might properly come last—because these very curves will serve to make the function of the storage battery more evident and intelligible. Some explanations should be made regarding the conditions of the case. This (Fifty-third-street) station is one of the supplemental provisional stations, as it were, the company has built in various parts of the city to help its larger station (Thirty-ninth-street, etc.) in supplying the rapidly increasing demand for current. These stations, at first comparatively small in capacity, gradually develop, and eventually become large stations when the patronage justifies. Their chief function is to relieve the other stations at the hours of heavy load, by delivering into the mains a certain amount of current

that would otherwise have to come, and at greater loss or "drop" from one or another of the stations connecting with the network of mains. Hence, the load may be varied, more or less arbitrarily, at these stations, according to the proportion of load that the larger stations are desired or able to carry. Telephonic or telegraphic connection serves to keep the various stations informed of the conditions at the others.

The storage battery, like the station itself, was installed provisionally and by way of experiment, as it were, without paying very strict attention to the size, capacity, or other conditions necessary to obtain the best results.

The battery is installed on the second floor above the engine and dynamo room, and consists of 140 cells each of about 1,000 ampere-hours capacity, weighing some 750lb., and of about 48in. in length, 21in. in width, and 15in. in length.

The battery has a normal discharge rate of about 200 amperes, but can be discharged, if necessary, at 500 amperes. The two curves show different applications of the battery. The first curve, Fig. 2, shows the station record for April 22, 1893. The station was then running only 12 hours per day, or from noon to midnight. The total load of all the stations being light in the afternoon, the larger stations could easily take care of it; hence the only station load from 12 to 5.45 p.m. was that required to produce only the charging current for the batteries. The plant was running at perfectly constant load, as shown by the straight line, *a b*. The lightly-shaded area below this line represents the current (ampere-hours) put into the battery. By 6 p.m., both the station machinery and the battery were delivering current into the mains. The curve *b d e f g* shows the total current. The curve *c h j k g* shows the amount delivered by the dynamos direct; the rest, or the difference represented by the relative heights of the two curves at any two points (say, *h* and *d*), was supplied from the battery. The heavily-shaded area between the two curves represents the amount of current put in by the battery. Calculation shows that the battery furnished about 23·2 per cent. of the total energy delivered to the mains. The maximum rate of discharge attained by the battery was about 270 amperes. Thus, in this case, we have an example of a battery which is used for the purpose, first, of giving a load to station machinery that would otherwise be idle; second, utilising the stored energy to increase the rate of output of the station at the time of heavy load, which would otherwise necessitate greater dynamo capacity. In the second curve, Fig. 3, five months later, the conditions have been changed. In the first place, the station output has increased greatly, being now about 2·9 times greater, and it is also continuous—*i.e.*, instead of delivering current into the mains only from 6 to 11.45 p.m., as in the first case, the current is now delivered continuously at varying rates represented by the curve *a b c c′ c″ e f g*. The station now runs from 8 a.m. one day to about 2 a.m. the next day, or 18 hours. When it starts at 8 a.m. it carries a twofold load: first, the regular load allotted to this station shown by the curve *c c′ c″ e*; and second, in addition, the load represented by the curve *d d′ d″ e*, which is the current absorbed by the batteries in charging. It is to be noted that the total load is much more uniform than if the station were feeding into the mains alone, for the extremes of current fluctuations shown by the curve *d d′ d″ e* represent a total variation of only 80 amperes on an average load of 850, or less than 9½ per cent.

I have been informed within the last few days by Mr. Pakenham that the battery is now being made to play an additional part of some interest. The maximum load, *f*, has increased to such a point that the station plant is no longer adequate; and consequently the battery is put on to "cap" the summit of the load and supply the excess of current required above the capacity of the dynamos. When the load begins to fall off (about midnight) a part of the plant is shut down; but since the load is still too heavy for the other dynamos, the batteries again serve to supply the excess (from *g* to *h*).

There is only one other case in this country—namely, the Edison station at Germantown, Pa.—where storage batteries are used as load equalisers. The total capacity there is of about 1,000 ampere-hours, made up of several series of small cells connected in multiple. The battery is charged during the six or seven early morning hours when the outside load is very light. It stands idle during the heavy load in the evening, and is discharged to carry the load after the plant shuts down. In this case the battery saves the expense of running the plant during the period of small load. Additional capacity is contemplated by the company, and will probably be put in this winter.

A large battery is being installed at the central Edison station in Boston. This battery, of German manufacture (Tudor), will be by far the largest in this country, the cells being over twice the size and capacity of the battery of those in the Fifty-third-street (New York) station referred to above. Its adoption was decided upon after a special study made of the use of storage batteries in European central stations by C. L. Edgar, the superintendent of the company. The Brooklyn (N.Y.) Edison station has also in contemplation the use of a similar battery.

It is in Europe, however, that the use of the storage battery in central stations has made the most headway.

In the city of London alone there are no less than eight stations supplying current for lighting in which storage batteries are depended upon for part or the whole of the load carried. The aggregate actual capacity of these stations is some 200,000 lights (16 c.p.). In many cases the batteries are not located in the generating station, but at sub-stations suitably located with reference to the consumers. The charging current is sent to the batteries at high potential, several sub-stations being joined in series for the purpose of charging.

In Paris there are some 20 or 30 such sub-stations located in various parts of one section of the city, and all charged from the same central station.

In the "Edison section" of the city an interesting application is made of a large (2,800 ampere-hours) battery, which is located at a point somewhat distant from the central station and connected with the mains from which it is charged at those hours when the load is light, by

taking current from the mains themselves, the potential being regulated by means of a continuous-current transformer. In this way a considerable amount of energy can be sent at a low rate, and, therefore, at small loss or drop of potential. This energy is used for maintaining the pressure in that portion of the mains, and for delivering a certain amount of current which would otherwise have to come from the station over heavily-loaded feeders (in the busy hours), and at greater loss of potential. Thus the battery, in this case, saves the cost of larger feeders, while it also furnishes a load for the hours of small load.

This plan suggests itself as of possible service in electric railway systems covering a large area of territory all fed from a single central station. The batteries could be located at distant points, or at such points as would give the best distribution of current to the trolley lines with the least expensive linework. The station machinery would then virtually work at constant load to feed the batteries, which latter would supply the power needed for the car motors. In this way, not only would an economy in the cost of conductors be effected, but there would be more uniformity of potential all over the system.

Table A gives some additional stations where storage batteries are used, with various data relating to them.

As regards the batteries used, the author stated that the principal object to be aimed at was long life and high efficiency even at the expense of increased first cost. The Planté process of formation and its modifications would seem to have proven itself superior to the pasting or Faure process, if one can make a criterion of the fact that at least nine-tenths of the aggregate of the central-station batteries used is of the Planté type, or some modification thereof. The Planté batteries are conceded to be, usually, of lower capacity per pound; but, on the other hand, they have the advantage of being able to carry heavier rates of charge or discharge.

There is probably no storage battery on the market of American manufacture having as much capacity as 500 ampere-hours. In Europe they can be procured up to 5,000 ampere-hours capacity. A cell of the latter capacity, weighing complete some 4,750lb., size about 36in. × 39in., height about 40in., gives an idea of the scale on which the use of storage batteries in European central stations is carried on. It may be added that a further idea of the scale of operation is obtained by examining the plans of central stations, such as that of Hanover, where a separate building with four floors about 70ft. by 35ft. is reserved for the storage batteries.

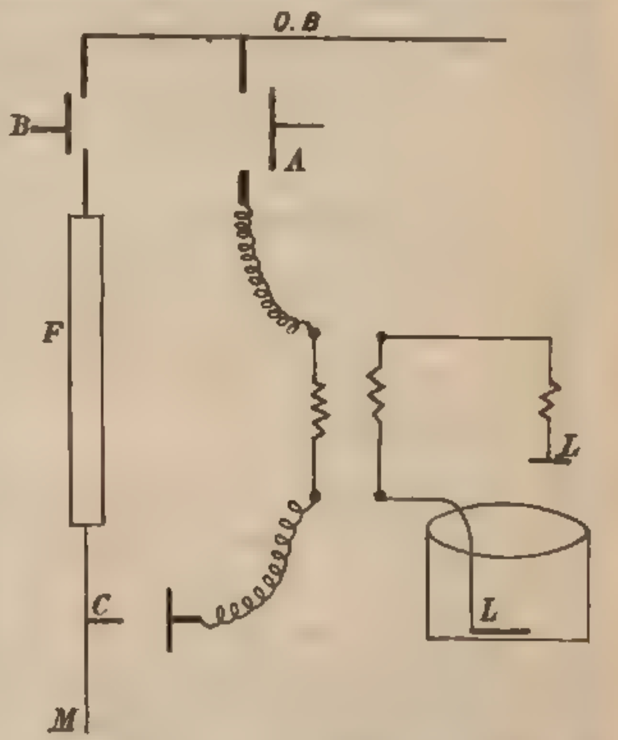
The author also referred to a number of curves showing how the capacity and efficiency of the battery varied with the rate of discharge. To illustrate by an example from actual practice he cites the station at Lyons, France, where the watt efficiency for one month averaged 85 per cent.; at Hanover, 78·4 per cent. for the entire year; at Dessau, 78 per cent.; in the Fifty-third street, New York, Edison station, 85 per cent.—the figures guaranteed by the makers, the Crompton-Howell Company. As regards the first cost of storage batteries the author found it difficult to obtain exact information. He gives a curve showing the variation in cost with increased size for the Crompton-Howell cells. The Electric Storage Battery Company, of Philadelphia, which is about to put on the market some large central-station cells (up to four kilowatt-hours) of a type already in extensive use in France, expects to reduce the cost to 25dol. f.o.b. per kilowatt-hour capacity. The total cost, erected, would be from 30dol. to 35dol., according to distance, etc. The cost of imported batteries, erected, would probably range, according to size, from 40dol. to 65dol. at the present time.

The maintenance is generally guaranteed by the manufacturer for a fixed annual percentage. At first this percentage was as high as 10 per cent. It was found, however, as the result of improvements that the percentage could be reduced safely. The present ruling cost of maintenance is about 5 per cent per annum for a 10-year guarantee. In every case it is stipulated that the battery will be put in as good condition at the end of the 10 years as when first installed.

The author has noted in every case investigated a scrupulous attention to details large and small of the installation of the batteries, and of their care and treatment, which contrasts greatly with the way storage battery installations have been usually treated in this country. This may, and doubtless does, account in part for the difference in results obtained. The information gathered on this point from all sources seem to warrant the conclusion that storage batteries require attention, not necessarily extensive or expensive, but regulated or systematic attention.

PUTTING ON TRUNK MAINS GRADUALLY.

In the brief report in our last issue of Prof. Fleming's speech at the Institution of Civil Engineers, we could only briefly refer to the method adopted at Deptford for turning the current on and off the mains. The method will be better understood from the accompanying diagram. It was first suggested, we believe, by Mr. Partridge, one of the staff at Deptford, and was successfully tested on 2,500 and 5,000 volt circuits before being discussed with Prof. Fleming.



The operation is as follows: Complete the primary circuit of a transformer in series with any main off the 10,000-volt omnibus bar by the plugs, A and C; lower the movable lead plate (shown by the top, L, in the diagram) into a tub of water gradually. As it approaches another fixed lead plate, L, in the water, it will short-circuit the secondary coil of the transformer. When the secondary is thus short-circuited, the plug, B, is put on which connects the trunk main straight through from the omnibus bar. The plugs A and C are then removed, and the movable lead disc pulled up for future use. For taking off the trunk mains the operation is reversed—viz., the movable lead plate is lowered to make contact with the fixed lead plate in the tub, short-circuiting the secondary coil of the transformer, the plugs A and C are put in, and B is taken off. The movable disc of lead is slowly pulled up out of the water and the plug A taken off, finishing the operation. The water-cask used at Deptford is an ordinary 40-gallon cask, and is filled with water to within some 3in. of the top. In the diagram, O B represents the 10,000-volt omnibus bar; F, the main fuse; M, the main to London; A, B, and C, plugs to make or break contact as described.

Indian Telegraph Rates.—The Indian Government have reduced the tariff per word on telegraphic messages between India and Europe to Rs. 3-4 *viâ* Suez and Tehara, and 5 annas less *viâ* Turkey.

Editorial and Publishing Offices :

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

A THREE-YEARS' SYSTEM.

Although the progress of electric lighting may be said to have been rapid, it might progress at a much greater rate if there were not certain initial costs to contend against. It was introduced as a luxury, succeeded as a luxury, and, like all luxuries, permeated downwards. Only a certain number of householders can contemplate without a pang the throwing aside of costly fittings and the purchase of new fittings to suit another illuminant. As we have often pointed out, the initial cost of the electric light is not only its own cost but the cost of the discarded gas fittings also. Of course, this does not hold when there are no gas fittings in existence, as in new houses. We hold—and our views are upheld by many householders—that the initial cost of, say, £100 to fix up the lamps is a great deterrent, and many hold aloof because of it. These people would gladly pay a moderate sum per quarter for a definite period, and could afford to do so when they cannot afford to pay a lump sum down. The dwellers in the smaller houses are usually less able to pay large sums than those living in large houses. Yet we feel quite sure that the addition of a number of small houses to the light load curve would assist very largely in levelling the curve. The number of lights on and off in the smaller houses is far more constant than in the larger, and, therefore, the demand would be more regular. It is well known that we have never gone into ecstasies over alternate-current distribution, and the more we look forward to general lighting the more clearly it seems that such a system has limits. Whatever may be said to the contrary, it will become more and more necessary to have a reserve in battery power rather than in dynamo power. At present the light is used by the wealthier classes, and the load is very irregular—the maximum being required for a very short time. Now, we contemplate lamps in a large number of small houses, where at the outside not more than a score of lamps would be wired, and where about four lamps would be in constant use from the time of lighting up to bedtime. These lamps would be required on an average all through the winter months for four to five hours in the evening, and half of them for an hour in the morning. The addition of a large number of such houses to the station supply would not get rid of the load-curve peaks, but would level up the other part of the curve. We think that the demand for the peaks must, sooner or later, be supplied by means of batteries. But to return to our immediate subject. Assume that the wiring of twenty lamps costs from two pounds to two pounds ten shillings per lamp—say, fifty pounds—a sum not worth a moment's consideration to many people, but one that cannot be entertained by others; yet the householder would very likely be ready to pay five pounds a quarter for three years for his fittings, or in many cases would pay the equivalent of a year's instalment down and the remainder in equal sums quarterly. There is any amount of money at the present moment in want of employment. Men are afraid to invest in the channels usually open, hence we are under the impression that a com-

pany founded for the express purpose of fitting-up houses in the manner indicated would probably get all the capital necessary. Of course, any fooling with promoters' and founders' shares would be absolutely fatal to success. It is probable, too, that in another direction an immense business could be done. We refer to motors, but this is too large a subject for us to consider at present. With regard to fittings, it has been suggested that the householder might leave without paying. Surely in that case the agreement would be so worded that the fittings remain the property of the company, and in the vast majority of cases the new tenant would undoubtedly take over the fittings under agreement, and would be glad to do so, because if the original tenant had paid any part of the price, the company would probably agree that when the balance had been paid the fittings would become the property of the tenant in possession. The suggestion has been made before, and, unless we are mistaken, was not long since in a fair way to be carried out—only the unforeseen occurred. Why do not some of the prominent members of the profession combine and set the necessary machinery in motion?

REVIEWS.

First Principles of Electrical Engineering. By C. H. W. BIGGS. London: Biggs and Co., Salisbury-court, E.C. Second edition.

The appearance of a new edition of any work is a matter upon which the reviewer can safely congratulate both author and public, inasmuch as it may be taken not only as proof of appreciation on the part of the latter, but as affording the former a sometimes welcome opportunity of profiting by the superior wisdom of others. In fact, it not unfrequently happens that in a second edition a good deal of the critic is bound up with the author. In this case it is not so, but those who are personally acquainted with the editor of the *Electrical Engineer* will no doubt admit that this exception to the rule is only what was to be expected.

In its revised and larger form, however, "First Principles" is undeniably a very useful book. The want of a work of a thoroughly practical character, written in simple language and giving the right information in a clear and concise way, has long been felt by the young engineer, to whom text-books are well nigh useless by reason of their superabundant technicalities and excessive range of subject. In "First Principles" the author may be said to have drawn a distinction between the electrical engineer and the electrician. He does not attempt to deal with telegraphy, telephony, or the more abstruse theories which govern the measurement and manipulation of weak currents. These, indeed, are subjects which could not well enter into a work intended solely for "engineers." By confining himself strictly to those laws and theories which apply to lighting and the transmission of power, the author has avoided much that might have been considered superfluous, and has at the same time been able to devote ample space to questions of undoubted interest and importance.

In one way the book is unsatisfactory. The chapter on "Distribution," for instance, is surprisingly brief, and secondary batteries are dismissed with a terseness which may be due to a fine contempt or, as the reader chooses, to the exigencies of space. These, however, are faults which may, and no doubt will, be corrected in a third edition.

Very interesting and almost original are the sections on the "Magnetic Circuit" and the "Interaction of Circuits." The author ascribes the earliest application of Ohm's law to the inductive "circuit" to F. C. Webb, and complains that while Ohm is immortalised no one ever hears of Webb. But he is quite wrong. Webb undoubtedly showed—some 30 or so years ago—that Ohm's law applied to the inductive circuit, but in this Gaugain anticipated him, and at a still more remote period—during the nineties of the last century—Walker made frequent reference to the "magnetic circuit," and in the published volume of his lectures will be found some excellent illustrations of lines of force, shown by the now familiar iron filings. Still, the theory is to all intents and purposes new. Few of the younger generation have heard of Walker, Gaugain, and Webb, and I am not disposed to deprive Mr. Biggs of his share of the credit, more especially as he can fairly claim to have invented the expression "loops of force"—an expression more descriptive and more correct than "lines of force"—and to have been the first to suggest the adoption of the line of force as a unit. These, however, are matters which are chiefly controversial, although they should claim the attention of every student who does not wish to be under the disadvantage of having to unlearn at some future time. There are not many things of greater importance to the engineer, old or young, than a proper understanding of the magnetic circuit, and it cannot be truthfully said that at the present moment our knowledge of the subject is exhaustive.

"First Principles" is nominally divided into six chapters, but the book is really contained in three—*i.e.*, "The Conductive Circuit," "How to Produce Electrical Pressure," and "Dynamos." The former includes an explanation of the phenomena which occur upon bringing circuits within the sphere of influence of each other, which is extremely valuable, and in Chapter III. the section on Electrographics is one of the main features of the work. I cannot help thinking that in the chapter on Dynamos, etc., more space might have been given to transformers and motors, but no doubt it is difficult within the compass of a two-and-sixpenny volume to amplify every detail.

THE ELECTROMAGNET.

Prof. S. P. Thompson has written a most admirable treatise on this subject. The author is evidently desirous of producing *the* classic on the subject, and in what he has done shows an immense amount of painstaking research. In view of future editions we may venture to suggest certain considerations and possible emendations.

On page 58 he says: "In former days magnetism was regarded as a surface phenomenon, resident (as an invisible fluid or fluids) upon these polar parts of the surface."

Unfortunately, our library is a comparatively poor one, hence Prof. Thompson may be able to prove all he says. Yet as far back as 1799, or close on a hundred years ago, the contrary to what he says was taught. If by his "former days" he means days more than a century ago, we give in, for we have no means of disputing the assertion.

In Walker's lectures, published in 1799, page 44, we read: "Is not this appearance favourable to the idea of an effluvium, flowing all round the magnet from one end to the other, and *having a circulation through* it." (The italics are ours.) Mr. Walker was led to this conclusion because of the behaviour of iron filings, and his diagrams are almost as complete and satisfactory as are those of Prof. Thompson himself.

As for the term "magnetic circuit," it is used again and again throughout the lecture.

Page 45: "A magnetic circuit is formed."

Page 45: "So soon as the bar *q* has completed the circuit."

We cannot find much clearer language in the most modern books, and if we are to give credit to anybody for opposing the doctrine of "surface phenomena," surely such an author as the one quoted deserves credit; but Walker's name does not appear in the index of Prof. Thompson's book. If any open-minded man will read the whole of Mr. Walker's lecture, he will probably be astounded at the knowledge displayed therein—remembering that "galvanic electricity" was then a thing of the future, as was the "electromagnet."

Coming to a later time—after Ohm had written his

paper and Sturgeon made his electromagnet—though Ohm's work does not seem to be known to the writer we are about to quote, that writer only needed it to have forestalled later-day writers in applying it to magnetism.

Dr. Roget, in his essay on magnetism, published in 1831, writes: "Thus it appears that the theory of magnetic attractions and repulsions is reduced to the same principles, *and leads to the same formulæ*, as the theory of electric forces in conducting bodies." (The italics are again ours.)

Is it not singular to find Roget's name wanting in Prof. Thompson's book? Surely, too, Roget and others before him no doubt knew about the magnet without poles—in the shape of a ring. If this is doubted, refer to paragraph 291, page 90, of Roget's "Electromagnetism." There will be found an illustration of a complete ring. But, as we say, "former days" is so indefinite that they may mean before 1831 or 1799. There are other historical statements which seem worthy of modification, but we shall have said enough if by these remarks we lead the author to generalise more or specialise more exactly.

LOAD FACTORS OF ELECTRIC TRAMWAY PLANTS.

BY FRANK B. LEA.

(Concluded from page 495.)

The extensive momentary variations (or "waves," as they have been called) in the load of an ordinary street tramway system are found to range almost inversely with the size of the system and the number of cars at work, or the regularity with which the latter are spread over the system. On a line where only a few cars are at work, the discrepancy between average and maximum horse power or output is naturally greatest; and here the latter may reach as high a proportion as three or four times the average. Where the output, on the other hand, runs into hundreds of horse power, the ratio is much less and tends to approach unity under favourable conditions.

In such a case the chief concern of the engineer is to provide means for "evening-up" the load curves showing the "tidal" variations—that is, to employ accumulators or other source of reserve power stored up during the hours of small load for use when the time of extra demand comes on—the generating plant (of a total capacity equal to but not more than the average) being kept going all the time at full load.

There is no need in this place to enter upon the much-discussed—and still unsettled—question as to the efficiency of accumulators; the report by Mr. Mailloux (already alluded to) touches upon this topic very fully, and should be referred to for a summary of our present knowledge and information. It is, however, worth while comparing the two methods, first, driving direct, with engines running for the greater part of the time at little more than half load, and second, employing accumulators with smaller engines at full load, from the standpoint of steam consumption, in order to show what saving, if any, can be effected in the coal bill.

In the case assumed, where the maximum output was 400 h.p., whilst the average only reached about 250 h.p., we may take for good compound condensing engines working at a little more than half load a consumption of steam per horse power hour equal to about 23lb., so that for 18 hours the total would reach 103,500lb. With batteries, we should have smaller engines of the same type running continuously at full load on a consumption of, say, 17lb. per horse-power hour, supplying the line direct for 11 hours with the full 250 h.p., and for the rest of the day affording about 100 h.p. for seven hours during the times of light load, with a balance of 150 h.p. for seven hours (or even assuming more than this, say 200 h.p. for nine hours so as to allow for recharging with an efficiency of 75 per cent. for the accumulator) as reserve power stored in the accumulator, sufficient for the "tidal" peaks.

This gives a total of about 89,250lb.—considerably less than with the larger engines running at half load; but of course other items besides the fuel account must be considered. The capital cost of regulating batteries of this type is very considerable, whilst the interest and depreciation may more than cover the saving in steam. Moreover, there is the serious difficulty arising from the difference in voltage between the charging and discharging battery currents; so that unless we employ accumulators of a much larger size than is absolutely necessary, the line voltage must vary in accordance, perhaps even more than when running direct.

These considerations will have different values in every line dealt with, and ought to receive separate attention, so that after duly weighing them a decision may be come to regarding the advisable use—or otherwise—of accumulators as appliances for regulating the load upon a tramway generating plant.

At present, all that can be said is that the plan of thus employing accumulators offers advantages of slightly greater extent than those given by a direct supply, even taking into account the additional complication of battery work and appliances. When we come to the question of levelling the "waves," however—as well as the "tides"—the conditions to be met are somewhat different, and require a separate treatment. In the early stages of electric traction, whilst its history is being made, we cannot, of course, expect to find it employed on so large a scale as future developments may show to be advantageous; and, therefore, the tramway engineer has to calculate a reserve not only for the fixed peaks in his load curve, but also for the rapid variations that come and go almost instantaneously throughout the day, and which are usually the greatest in a small system.

Although accumulators have long been used for the purpose of steadying the load from central stations for electric lighting (where, as already shown, the "wave" variations are comparatively slight compared with those occurring in an electric tramway station), yet it is doubtful whether they will act quite so satisfactorily in levelling "waves" that vary from 50 per cent. below to 100 per cent. above the normal average in as brief an interval as two minutes. Certainly, the writer knows of no instance where this has been done for any length of time.

The suggestion, first made, I think, by Mr. Kapp, that separate "flywheel motors" should be employed at different points upon an extensive system to act as reserves of power for very short intervals of time, is of a much more practical nature, and without any doubt will prove worthy of adoption when electric tramway engineers have learnt to consider every detail of their plant, however trifling.

So far as the "wave" variations are concerned in the line assumed for consideration, it may be necessary to allow for a difference of, say, 150 h.p. in the output in the space of a minute or two, and it is for coping with such differences where the load comes on and off instantaneously—that a heavy flywheel is most suitable. If the tramway system be concentrated rather than scattered, there is no reason why this provision for reserve power should not be made in the generating station, where it is an easy matter to arrange for a heavy pulley on the engine or dynamo shaft.

Where, on the other hand, the line is of considerable length and spread out somewhat widely, separate sub-stations may be advantageously provided, containing each a suitably wound motor operated from the line mains, and serving to rotate a flywheel of sufficient capacity for the extra demands on that section. The waste of power in such an arrangement is trifling, and little or no attention becomes necessary as compared at least with battery sub-stations.

The energy afforded by a flywheel employed in this manner is, of course, dependent upon several factors—weight, speed, and diameter—and to give the amount of reserve power necessary upon our typical line—viz., 150 h.p.—it would be sufficient to provide a couple of flywheels, each, say, of 6ft. mean diameter, with a weight of four tons, and allowing the speed to drop from 700 revolutions to 500 per minute. From 80 h.p. to 90 h.p. might thus be obtained in each wheel, or enough to carry the load safely over the peaks representing the positive amplitudes of the load waves, taking the line of average output as a base.

When the levelling process can be carried on at the generating station, it becomes a simple matter to increase

the storage capacity of the flywheels usually employed with the prime movers, of whatever type the latter may be. On the City and South London line, for instance, the engine flywheels, or driving pulleys, have a diameter of 14ft. and a weight of 14 tons, which, moving at a speed of 100 revolutions per minute, serve to store up some 2,500,000 foot-pounds of energy—an amount which ought to be sufficient to maintain fairly constant speed over a range of 80 h.p. variation in a single minute of time, even with slow-running engines.

With prime movers coupled direct to the generating dynamos—such as are now most generally employed—the flywheels may similarly act as energy stores; perhaps, indeed, even better, because the slip and other losses of belting are avoided altogether, instead of being increased; by reducing the diameters in proportion as the engine axle speed increases, suitable pulleys will give the necessary reserve, whether the engines are of the Willans type, running at 300 or 400 revolutions per minute, or steam turbines with 10 times the speed. The calculation of sizes and weights is a mere matter of arithmetic, which need not be dealt with here; any pulley manufacturer's list will give the limits of speed for different materials with a proper factor of safety as regards the breaking strain.

When a belt or similar connection between engine and generator dynamo is employed, there seems no substantial reason why a heavy flywheel should not also be arranged on the dynamo axle; there is at any rate no doubt that in the generating plant of both the Liverpool Overhead Railway and the South Staffordshire Tramway, the massive grooved rope pulley, mounted on each dynamo spindle with a third bearing outside, must exercise a considerable regulating effect upon the variations in the load required from the engines.

With regard to all these plans of arranging flywheels as regulators, it must be remembered that the essence of their successful operation is the extremely short period of time during which they are called upon to act. It is only for 20, 30, or 40 seconds, or at the most a single minute, that the maximum load comes on, and probably long before the reserve of energy contained in the revolving flywheels has been used up, the automatic expansion gear on the steam-engine will have retarded the cut-off sufficiently to make up the engine power to the extra amount required.

A few remarks, in conclusion, may be made with reference to improving the load factors of tramway plants by careful attention to the energy *receivers* as well as the energy *generators*. So far, our only consideration of the subject has been from the station end: it is, however, to be noted that the chief causes of excessive variation in the load of a tramway generating plant are first and foremost the heavy calls at starting or running uphill; whilst in addition the state and arrangement of rails and permanent way generally will have some effect upon the total power required.

The first of these causes *may* (I do not say *will*) be largely removed if some satisfactory arrangement of variable gearing on the car is devised. On this point, it is much to be regretted that no extended practical results of a system like that of Beaumont's are as yet available. Until, however, we have at hand some reasonable experience of these devices, it is no use remarking how theoretically admirable they may be.

With regard to the second—and much less important—cause of load change, the details of any remedial measures are rather ouside the scope of this article; they involve so many considerations that separate treatment would alone do the matter fully justice. Perhaps, when their importance requires it, this may be done.

INSTITUTION OF ELECTRICAL ENGINEERS.

THE ELECTRICAL TRANSMISSION OF POWER FROM NIAGARA FALLS.

BY PROF. G. FORBES, F.R.SS. (L. AND E.), MEMBER.

(Concluded from page 491.)

It will be obvious from this design, considering that the speed of revolution is 250 per minute, that great care has to be devoted to the balancing of the revolving parts. Everything has to be calculated not only for a speed of 250 revolutions, but for double that amount, which is the maximum speed at which the turbines could possibly run—at which speed they might run through a breakdown of the governor, although this is an accident almost impossible to occur. Each of the revolving parts will of course be balanced individually, and I have suggested a plan for the final balancing which seems likely to be effective. A temporary bushing would be put in the bearings of india-rubber lined by a thin metal tube. The dynamo would then be rotated slowly and the balance adjusted in the usual way. The speed of revolution would be gradually increased—a new adjustment being made at each speed—until a speed of 500 revolutions a minute is attained, and when an adjustment has been made at this speed it is pretty sure that the balance at 250 revolutions per minute will be very perfect, and the mechanical friction reduced to a minimum. As stated before, the oiling arrangements have been introduced, not only to ensure higher insulation and to preserve the insulating material, but also to lower the temperature as much as is possible, because every step we take in the reduction of temperature is an advance. These oiling arrangements may perhaps be adopted in the future, but at present we are not making use of them in the machines which are in process of construction. When we have had experience with these we may in future adopt the oiling arrangements; and as there is likely to be a great development in the direction of electric transmission of power in connection with the utilisation of water power in many parts of the world, it has seemed well to me to put before you these details, so that they may be considered in other cases that may arise. At a meeting of the Board of Directors in New York lately it was resolved, on the recommendation of the consulting engineers of the company, that the contract for two or three alternators, each of 5,000 h.p., should be assigned to the Westinghouse Electric and Manufacturing Company, of Pittsburgh. I would wish to state how much we owe to Mr. Westinghouse, and to his chief engineer, Mr. Schmid, for the zeal with which they have taken this matter up, and their desire to meet our views and to secure for us machines of which they felt they could guarantee the satisfactory performance.

Before leaving the subject of the dynamo, I would wish to point out that it has been designed for special circumstances in connection with the Cataract Construction Company's work. If a dynamo of the same type were being constructed for another place it is certain that modifications would have to be introduced. I particularly draw attention to the fact that some trouble in getting out a good mechanical design arose from the necessity which existed of being able to provide a clear space of about 5ft. diameter in the middle of the machine without taking the whole machine to pieces, the object of this being to enable us to lift up portions of the turbine shaft which it might be required to put into repair. In any case where the long shaft existing in our case is not required, the design of the dynamo is much simplified, and would more nearly approximate to the first design of which a drawing is shown, but arranged for 33 periods a second. If the present paper were intended to relate solely to the subject of the utilisation of power at Niagara Falls, I would be content with describing what has actually been done, but I foresee that there is going to be a great development in utilisation of water power, and its electrical transmission. I am therefore inclined to say a few words on some other details which we have been carefully considering, but about which no definite decision has been arrived at. Before doing this, I would direct your attention to the drawing representing a plan of our power-house, in which you will perceive the inlet passages, A, from the great canal, B, which draws its supply of water from the upper river. From these inlet passages, the iron pipes, or flumes, C, pass vertically downwards to the bottom of the great wheel pit, which is a slot cut in the ground to a depth of nearly 200ft., at present large enough to contain four turbines in line, but which can be extended to a much greater length, the whole capacity of our tunnel being 100,000 h.p. The drawing shows circles, D, in the plan, which indicate the position of the turbine and dynamo above it; and the position of a hatchway, F, by which materials can be raised or lowered. It will be noticed that between the inlet channels and the wheel-pit the flumes are bent downwards, and thus leave a V shaped space, G, which I have appropriated to make a subway, running along the whole length of the power house, to carry the high pressure conductors. It will of course be understood that the slot forming the wheel-pit is arched over at the top to form the floor of the power house, upon which the dynamos rest. It will be noticed that at the north end of the power house there is a large square chamber, H, in which I propose that all the measuring instruments and other apparatus under the control of the chief electrician shall be assembled. Underneath this chamber there is a cellar, in direct communication, first, with the subway which I have described as existing in the power house, and second, with the subway which leads outwards from the power house at present as far as the Pittsburgh Reduction Company's works, and may possibly eventually lead to Buffalo. In this cellar all the high pressure wires, the transformers, the artificial load, and other high pressure machinery, will be placed. It will be noticed that other spaces are left in the floor forming trenches along which the conductors can be carried. With these arrangements there can be no possibility of danger to any person in the power house; and if any wires are to be found laid along the walls of the power house or elsewhere, I wish it to be a maxim that we shall be able to place upon these wires a card marked "No danger," so that there will be no possibility of danger from any person touching anything in the power house.

With regard to the exciting current, the best plan available at this moment is to use one of the machines which are generally

known as the Schuckert machines for converting the alternating into a continuous current, transformers being inserted in order to lower the pressure. In order that the exciting current may increase with the load, it would be well to make these transformers of special construction, each having two primaries and one secondary. One of the primary coils would be in series with the main circuit, and the other in shunt. I would furthermore make these transformers sufficiently large to deal with all the dynamos which are in the central station, and I would subdivide the secondary coil into sections, to enable us to cut out a section of the transformer when we cut out one of the dynamos. When we wish to cut out a dynamo, a switch would be worked which would at the same time short circuit the field coils of that dynamo and also cut out one section of the secondary of the transformer which is supplying the exciting current to all the dynamos. This plan allows the fields of all the alternators to be put in series—a desirable arrangement for parallel working. A resistance may, of course, be put in circuit with the fields of the alternators for regulation.

I presume it will be taken for granted that in any large work of this sort the primary circuit should never be broken when in action. For my part, I hold that this should be the case even in smaller stations.

An important feature for putting the dynamos in parallel, and for removing a dynamo, is an artificial load. It is desirable that this artificial load should consist partly of a resistance and partly of self induction. It is only by this means that the dynamo which is going to be put in circuit can be brought to exactly the same condition as those which are working, both as regards volts and amperes. It may be well to describe the operations which take place when a dynamo is switched in parallel with the others. First, connection is made between the armature and the artificial load; then the exciting switch is turned so that an extra section of the transformer is put into play, and the short circuit on the field coils of the dynamo is broken. The dynamo being excited, the turbine is then started, or this may be done at first. The artificial load is then adjusted until the dynamo is giving the same volts and amperes as the others. A synchroniser is then placed between the artificial load and the external circuit, and so soon as synchronism is attained a switch is closed which connects the artificial load with the external circuit. Resistance is then put into the artificial load until there is very little current going through it, when it is switched out, and the dynamos are all working in parallel. To cut out a dynamo from the circuit the operations are performed in the opposite order. The artificial load with high resistance is put in connection with the external circuit; this resistance is gradually diminished until it indicates the amount of work that is being performed by one dynamo: the connection between the artificial load and the main circuit is then broken, leaving the dynamo (which is being switched out) feeding the artificial load. The resistance of the latter may then be increased, and the exciting switch actuated so as to short circuit the fields of the dynamo, and to remove one section from the secondary of the exciting transformer. The supply of water to the turbine may then be shut off.

If machinery is worked, even at 20,000 volts, in the manner I have described, there is no possibility of injury from any great rise of electrical pressure, unless the external circuit be by any means accidentally broken. To provide against this sort of trouble I would have wires coming from the external circuit where it enters the power house connected through a large resistance, or through the primary of a transformer the secondary of which contains a resistance. In circuit with it I would have a break consisting of two carbon points at a distance of about half an inch apart if we were dealing with 20,000 volts, so that an arc could not be formed unless the pressure rose above the normal value. Under these circumstances, so soon as any resonant effect due to the breaking of the circuit or due to any other cause raises the electric pressure above the normal, an arc is established across the carbon points, and so a load is put on which removes the cause of the extra high pressure. This is the only automatic means which I have been hitherto able to think of which is sufficiently rapid in its action to overcome any possibility of injury to the dynamo or transformers.

I have attempted in the course of this paper to give you some idea of the work which has been actually done or decided upon at Niagara Falls, and also to show you the views to which I have been led by any special experiences which I may have had as to the general ideas which ought to guide us in the construction of plant in the future for transmitting power to a distance electrically.

In describing the different plans which are available, I have avoided mentioning the names of those numerous electrical engineers and manufacturers who, by their inventions, researches, or applications, have advanced the art; or discussing their claims to priority but I cannot conclude this paper without mentioning the names of some of those who, in one way or another, have made great steps in the applications of alternating currents to power purposes. I would particularly mention the names of Messrs. Ganz and Co., Mr. Schuckert, the Allgemeine Elektricitats Gesellschaft, of Berlin, the Oerlikon Fabrik, and Messrs. Brown, Boveri, and Co; also Mr. Eickemeyer, Mr. Ferranti, Prof. Ferraris, Prof. Fleming, Dr J. Hopkinson, Messrs. Hutin and Leblanc, Mr. Rankin Kennedy, Prof. Mengarini, Mr. Mordey, Mr. Tesla, Prof. Elihu Thomson, and Mr. Henry Wilde. I feel that all of us owe a great deal to their work.

In conclusion, I wish to draw attention to the figures which show the relative merits of high and low frequency with polyphase motors.

Everything is identical in the two figures, except that—the frequency of one (a) being double of the other (b) a has 16 poles, b has 8. The armature is identical in both, and revolves at the same speed and does the same work; and the field revolves at the same rate in both, and the induction and current density are the same. The differences are that a has more copper and less iron than b. The comparison of efficiency depends on the depth of both. As an example, assume that a has 50 per cent. more copper in the fields than b, the ampere-turns per pole being necessarily the same in both, and that b has 50 per cent. more iron than a, and that the hysteresis loss in b (= H_b) is equal to the resistance loss in its copper coils (= C_b). The values for a are

$$H_a = 2 \times \frac{2}{3} \times H_b ;$$

$$C_a = \frac{3}{2} C_b ;$$

$$H_a + C_a = \left(\frac{4}{3} + \frac{3}{2}\right) \frac{H_b + C_b}{2} = 1{\cdot}42 \times (H_b + C_b).$$

Thus the total losses in the field of higher frequency (neglecting eddy currents) are 42 per cent. more than in the field of lower frequency.

DISCUSSION.

(Continued from page 491.)

Mr. G. Kapp, continuing, said that the result was that if they compared different systems of transmission, they must have a basis of comparison. The basis which he took was the practical one of working, or, rather, putting it as a primary condition that the systems compared should have the same safety as regards insulation. The system that Prof. Forbes recommended as economical was the worst; with continuous current 100 tons of copper were required, with alternating single or two phase 200 tons, and three-phase 250 tons, the two-phase with three wires requiring 290 tons, and being entirely out of the question. He knew of no gain of 3 per cent. by reducing the frequency. With regard to synchronising motors, even if two rings were put upon the commutator how was the motor to be started? A Tesla motor must be put down to do it. If they had to do that, they might just as well use a Tesla motor. There were single and multiphase motors on the market, but he thought the electrical journals had served them badly by not fully dealing with the three-phase system. He had tested a single phase motor, and the following was the result: The machine gave on the brake 882 watts, and it ran at about 1,800 revolutions. The frequency varied between 60 to 67; the commercial efficiency was 60 per cent., and the power factor 74 per cent. At starting, the current to produce the torque equal to its full output was 2¼ times the normal working current. The weight of the machine was under 1cwt per horse-power. With regard to Prof. Forbes's type of alternator, he thought it was about the best machine that could be made for that particular job. The speaker had worked out a machine adopted by the author, and the following was the result:

5,000 H.P. ALTERNATOR—250 REVOLUTIONS.

Frequency	16·6	33·3
Number of poles	8	16
Volts on open circuit	22,200	21,500
Losses per cent	2·145	1·660
Armature plates, pounds	32 000	20,500
Magnet ,, ,,	12 000	10,000
Yoke ring ,,	38,500	18,200
Field copper ,,	7,200	7,000
Armature copper ,,	5,500	2,500
Total	95,200	59,100
Pounds per electrical horse power	19	11·8

The machine worked out to a weight of 19lb. per electrical horse-power with a frequency of 16, and 11·8lb. with double the frequency.

Prof. S. Thompson congratulated the author on the step forward in our appreciation of the problem of the utilisation of power such as that of the Falls of Niagara. He could not quite understand the apologetic tone adopted by Prof. Forbes throughout the paper as if he should not have given reasons for not having adopted the continuous current, and yet he had been coming to it by adopting the low frequency. With regard to the difficulties of working stations from sudden rushes of current when a field was thrown in or out, all station work tended to simplify this, and although switches were provided, yet one knew that in practice a large current was not broken. All station engineers fell in the way of operating that enabled them to slow down their engines or something else to prevent a large rush of current when the switch was closed. He did not think the curve of efficiency of alternating current motors was to be accepted without hesitation. He was glad that the works at Niagara had not been called a central station, which was misleading but a power station.

Mr. J. Swinburne observed that the first point that struck him was not the purely electrical question, but the commercial one—namely, what was the power going to cost, what would it be sold at, who were the persons that wanted it, and what were they going to do with it? The cost of the power was not given in the paper, and the question was very curious. In most industries the power used was quite a small proportion of the cost of running a factory, in others it was a large proportion. In tearing up wood pulp power was a serious matter, but not in flour milling. Some time ago, in conjunction with Mr. Thwaite, he worked out a

scheme for transmitting power from the Midlands to London. He found that the interest and the capital was so enormous as compared with the cost of coal as hardly a fact to be at all considered. As to those who were going to use the power, the problem was entirely different where it was wanted to supply a lot of small users requiring $\frac{1}{10}$ h.p. to ventilate their eating houses, and drive away flies or run printing machinery with power of from 1 h.p., 2 h.p., or 5 h.p., or wherever they wanted to operate aluminium works requiring hundreds of thousands of horse power. There was no difficulty in making motors for large powers. The difficulty of starting did not come in with very small motors; the only difficulty was with those of medium size. Discussing the question of frequency, he said that it very much depended upon the class of consumers who were going to use the motors. With regard to the extra output from a double current, the matter was considered as early as in 1887 at Messrs. Crompton's, when an enquiry for a large power transmission in Australia was discussed. The alternating current was settled upon, and Mr. R. B. Rogers suggested at the time that the best way was to use a double current. In fairness to Mr. Tesla and others, he mentioned that he did not think that Mr. Rogers realised that this double current plant would be self starting. The extra output was a little illusory when large machines were dealt with. He protested against a large number of statements of a general character, such as "a high frequency is a good thing in a given case, all other things being equal." He would like to say much about dynamos in parallel, but it would take an evening or so to discuss the matter. The question was not entirely one of the dynamo, but everything else had to be taken into account. Some years ago he investigated the matter of a frequency of 25, and found that he was wrong.

Mr. S. F. Walker asked the cost of the half-mile of culvert. It appeared to him that towns here would come to that method, where a man could walk upright and examine the cables. The speed of the alternators, which were very heavy machines, appeared to be high.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE V.

(Continued from page 498.)

Heating Air before Use in Motors.—The amount of expansion which can be permitted in air motors, without inconvenience from the fall of temperature, is limited. Any difficulty thus arising is obviated if the air is heated immediately before it is used.

Quite apart, however, from the removal of a practical difficulty, the reheating of the air before use is of the greatest economical importance. The air when heated expands, and more work is obtained in the motor per pound of air used. Whether it is economical or the reverse to heat the air before use depends on this—whether the additional work obtained is more or less valuable than the coal expended. Experience shows that it is extremely advantageous economically to reheat the air. The heat supplied is used with great efficiency, and a larger fraction of it is converted into work than in ordinary heat-engines. Further, very small, easily managed, and simple reheating apparatus can be employed. A simple coil of pipes, with a small furnace capable of heating the air current to 300deg. F., may increase the work done per pound of air by 25 or 30 per cent. The heat, according to the experiments of Riedler and Gutermuth, is used five or six times as efficiently as heat supplied to a good steam engine.

Fig. 28 shows a simple form of reheating oven. The compressed air passes through a double spiral pipe, C. The furnace gases rise through the centre of the coil and descend on the outside in a cast-iron casing, with a spiral diaphragm or rib. The grate is at F. The air discharged from the motor, M, may be used to create a chimney draught. This has the advantage that the draught varies with the amount of work done. As air does not readily take up heat from metal surfaces, it is advantageous to introduce a small quantity of water into the spiral pipe of the reheater. The water is evaporated into steam, and in the motor the steam condenses, giving back the latent heat to the expanding air. The water may be supplied from a reservoir above the oven, to which the air pressure is admitted, so that the water descends into the heater by gravity. The reservoir can be refilled by shutting off the air pressure. Steam thus used is extremely efficient in increasing the work done by the air, and probably the moisture in the cylinder helps to prevent wear and leakage.

In some simple reheaters, tested by Prof. Gutermuth, in Paris, the air was heated from temperatures of 45deg. to 122deg. up to temperatures of 224deg. to 303deg. From 8,035 to 10,070 thermal units were given to the air per pound of coal used. About 5,200 thermal units were transmitted to the air per hour per square foot of heating surface.

Combination of a Gas Motor and Air-Engine.—In a scheme for distributing power chiefly by compressed air, for the town of Dresden, Dr. Proell proposed to work an electric lighting station partly by air motors and partly by gas engines. The ordinary reheating apparatus for air motors is not very convenient in this case, in consequence of the great variation in the demand for power. Hence Dr. Proell adopted the plan of combining gas-engines with air motors. The gas-engine is itself a very efficient and convenient motor for an electric lighting station, because it can be put in action or stopped, according to the variation in the demand for power, and there is no waste like that due to keeping boilers in steam ready for use. But in gas engines a very large fraction of the heat developed is necessarily wasted in the water-jacket. Dr. Proell proposed to abolish the water jacket, and to take the compressed air through the gas engine jackets, to reheat it on its way to the air motors. In addition, the hot gases rejected from the gas engine were to be used in the jacket of the air motors. Undoubtedly by the combination of the gas engine and the air motor, a quite remarkable thermal efficiency could be obtained.

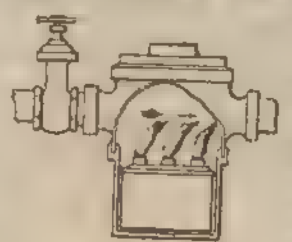

FIG. 29.

It may be questioned whether it would not be better to take the exhaust of the gas engine directly into the air current. Then the gas engine would work with a heavy back pressure, but the work so lost would be recovered in the air motor. In a paper on compressed air,* the author suggested reheating by the burning of gas in the air current, so that the whole of the heat would be utilised without chimney losses. Some attempts have since been made in this direction in America. Fig. 29 shows a small petroleum burner used in the air-main supplying compressed air to rock drilling machinery.

Meters for Measuring Air Supplied to Consumers.—Various types of meters have been used in compressed-air systems. Very accurate displacement or positive meters can be constructed, but they are costly; hence inferential meters, which are virtually air turbines driven by the air current, are more commonly used. Fig. 30 shows an arrangement designed by Mr. Abrahams, of the Birmingham Compressed Air Company, which is stated to have worked with an accuracy within 1 per cent. With a simple fan or turbine, driven by the air current, the velocity of the meter is not proportional to that of the air current in consequence of the friction of the meter. If set to be right, at a mean velocity, it over-registers with a fast current, and under-registers with a slow current. Mr. Abrahams added a kind of pendulum governor, the balls being replaced by hemispherical cups. The governor creates a resistance increasing with the radius of the circle in which the cups revolve, and therefore with the speed of the meter. This extra resistance may be made to balance the tendency to over-register.

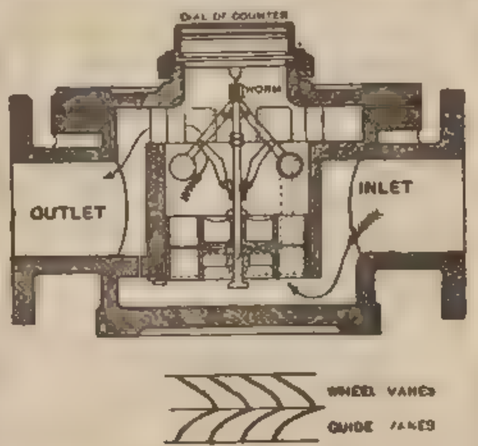

FIG. 30.

Distribution of Power by Compressed Air at the Works of the Societe Cockerill at Seraing.—The great works at Seraing may be considered the birthplace of modern compressed air machinery. The compressed air plant for the Mont Cenis Tunnel works was made at the Cockerill Works, having been designed and constructed under the direction of Mr. J. Kraft, who is now at the head of the engineering staff of the works. In conjunction with M. Sommeiller, Mr. Kraft carried out extensive experiments on the efficiency of air compressing machines in order to obtain the necessary data as a guide in attacking what was then a new problem. Compressed air in mines was first used and is still extensively used at the Marihaye Collieries at Seraing. Further, since 1854 compressed air has been used in the engine works of the Societe Cockerill for working cranes.† With regard to this last application, Mr. Kraft states that "it might be expected that the losses of power incurred in the production and utilisation of compressed air would cause it to be rejected as a motive power. But in many cases it is not so—for instance, for a series of cranes, machines working only at intervals, where steam is used, enormous losses are caused by condensation in the pipes; and expansion and condensation can hardly be used in the engines; whereas, on the other hand, compressed air can be produced by high class engines consuming very little coal. In this way, the loss incurred by employing air may be compensated for. For a set of cranes like those at the Cockerill Works, or at Portsmouth Dockyard, steam cannot compete with air. The principal rival of compressed air is water, and there are many cases where water is to be preferred. For cranes placed in the open air in cold countries, the great impediment to the use of water is frost. For the installation of a number of cranes in the open air, along a quay

† "Notes on Compressed Air and Machinery for Utilising it." By John Kraft. *Proceedings* Institution of Civil Engineers, vol. lxxxix.

wall, Mr. Kraft thinks that air is preferable, as in the case of Portsmouth Dockyard." The compressed air machinery erected in the engine works at Seraing in 1885—and still in use—consisted of the following machines: (A) Air compressing engine, with two cylinders. Diameter of steam cylinders and air-cylinders, 13·78in.; stroke, 29·53in.; revolutions per minute, 26. (B) Air reservoirs (two). Length, 36ft.; diameter, 6⅝ft.; maximum pressure, five atmospheres; diameter of pipes, 2in. (C) Forty ton travelling crane, with two double cylinder air motors. Diameter of cylinders, 4·53in.; stroke, 7·09in. The air is supplied to the traveller by a flexible pipe, which coils on to or off a drum, as the traveller approaches to or recedes from one end of the building. The crane has worked very satisfactorily, and was at work this year (1893). (D) Three four ton swivel cranes. (E) Air motor working hydraulic pumps for wheel press. (F) Twelve 12-ton swivel cranes. (G) Two 15 ton swivel cranes.

The compressing engine stops automatically when the pressure reaches 73lb. per square inch, and begins working again when the pressure falls. The air cranes differ in no respect from steam cranes, so far as their engines are concerned; and all can be worked with a pressure of 45lb. per square inch. Also an overhead traveller, with a reservoir of air at 90lb. has been erected in the foundry. The air is supplied to the engine through a reducing valve at 40lb. per square inch.

Compressed Air in Mines.—One of the largest mining plants worked by compressed air is that at the Chapin Mine, Michigan.* About three miles from Iron Mountain at Quinesec Falls, on a head of 52ft., 1,700 h.p. is obtained by four turbines. Each of these drives two Rand compressors. About 2¼ million cubic feet of air are supplied per day at 60lb. per square inch gauge pressure. From the compressor plant, a 24in. wrought iron main, ⅜in. thick, extends for three miles, an expansion joint being used at every 480ft. The air main is connected to the machinery, and to 105 power drills at the Chapin Mine, and also to some neighbouring mines. Most of the machinery is arranged so that by closing one valve and opening another a change can be effected from working by air to working by steam.

System of Transmitting Motive Power by Vacuum.—An interesting plant for distributing motive power by vacuum was established in the Rue Beaubourg in Paris by MM. Petit and Boudenoot. The general object in view was the distribution of power to small industries. From 1874 M. Petit had the idea of transmitting power by vacuum. In 1882 an association was formed and machinery erected. Conduits were laid communicating with the houses of consumers, who paid a rental based on the number of rotations of their machines, ascertained by a counter. The users of power were interested in the success of the scheme by participation in the profits. The working hours are from 7 a.m. till noon, and from 1 p.m. till 8 p.m.

* See the "Iron and Steel Institute in America," p. 378.

A steam-engine and exhausting pump of 70 h.p. to 80 h.p. was first erected, the mains extending 300 to 400 yards. Now there are three steam-engines, developing altogether 300 h.p., and the mains extend 850 yards. There are about 150 small motors on the mains. Part of the power is rented to an electrical company. This power is supplied by a fourth engine of 100 h.p. M. Boudenoot gives the preference to a vacuum system, because the cost of machinery is less than for a compressed-air system. The mains are always dry, and do not require draining boxes. Lastly, the efficiency of a vacuum system is greater. M. Boudenoot takes the efficiency of the exhausting pump at 0·93, the mechanical efficiency of the vacuum motor at 0·60, and the efficiency of the expanding air in the motor at 0·85. The resultant efficiency is then

$$0{\cdot}93 \times 0{\cdot}60 \times 0{\cdot}85 \times 0{\cdot}95 = 0{\cdot}45.$$

This, for small motors, is a good result. The exhausting cylinders make 20 to 50 revolutions per minute, and maintain a vacuum of 0·67 to 0·80 atmosphere. These cylinders have spray injection. The motors are constructed to supply 360, 540 and 900 foot pounds per second. There is a vacuum reservoir 50in. in diameter and 140in. in height attached to each motor. The vacuum mains are 10in., 8in., 6in., and 4in. in diameter. The house service pipes are of lead.

(*To be continued.*)

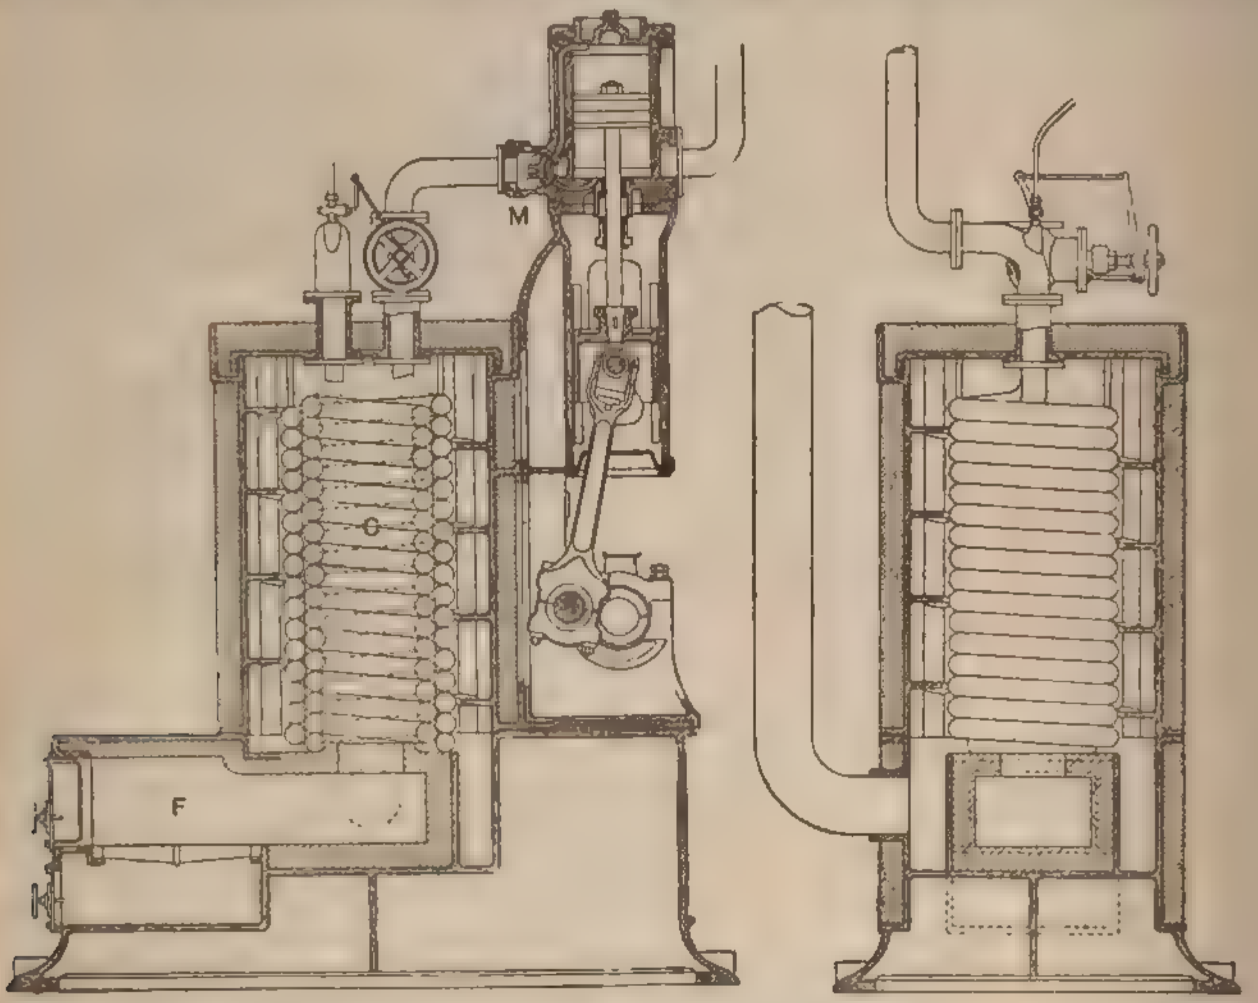

Fig. 28

PHYSICAL SOCIETY, Nov. 24, 1893.

Prof. A. W. Rücker, M.A., F.R.S., president, in the chair.

Colonel Maitland, C.B., was elected a member of the society.

Prof. S. P. Thompson then occupied the chair whilst the **President** read a paper "**On the Magnetic Shielding of Concentric Spherical Shells**." In this mathematical investigation the author considers cases in which the equipotential surfaces are surfaces of revolution about a line through the centre of the shells, and the permeability, μ, of each shell is constant. Taking the common centre as origin, the potential within any shell is expanded in terms of zonal spherical harmonics, and the ratio of the shielded to the unshield field determined. The following important result is arrived at—viz., if the permeabilities of the enclosed and external space be the same, then the ratios of the shielded to the unshielded fields are the same for each harmonic term, whether the part shielded be external or internal. It is also shown that the shielding effect on external space when a small magnet is placed at the centre of the shell is the same as the shielding effect on the enclosed space when the shells are placed in an uniform magnetic field. The case of a single shell with a small magnet at the centre

is next considered where the permeabilities of the internal and external spaces are taken as unity. Here the shielding depends on the ratio of the outer to the inner radius a_1/a_0. When the thickness of the shell is $\frac{1}{10}$ of a, the ratio of shielded to unshielded field, ψ_i/ψ_0, is $\frac{1}{12}$ when $\mu=500$, and $\frac{1}{24}$ when $\mu=1{,}000$. For $\mu=1{,}000$, increasing the thickness from $a_1\frac{1}{10}$ to $a\frac{1}{4}$ changes the shielding from $\frac{1}{24}$ to $\frac{1}{102}$, thus showing that after the shell is moderately thick further increasing the thickness is not very effective. When the small magnet is displaced from the centre of the shell with its axis along a radius, then the shielding effect of the shell is greater on the side towards which the magnet is moved, and less on the opposite side. Thickening a single shell being inefficient, the effect of using two or three shells separated by air gaps is investigated. Here, as in the case of a single shell, the shielding is improved by adding permeable material either within the inner or without the outer shell. If the inner and outer diameters are given, then, when the difference in these diameters is small, one continuous shell gives the best result. For a larger difference, two shells operated by an air gap are much more efficient than a single one, and filling up the air gap would appreciably diminish the screening effect. When the permeability of the substance is high, the best shielding is obtained when the radii of the bounding surfaces of the shells are in geometrical progression. The great value of lamination is shown in the following table, where the volume of the permeable material is expressed in terms of that of the enclosed space, and the shielding in each case being the best:

	Volume of material used.	External field.
Single shell	1·0	0·018
Two shells	5·0	0·0008
Three shells	4·8	0·00016
Single shell	7·0	0·0102

The conditions for the best arrangement in each of the following cases are fully worked out in the paper, viz., two shells where the largest and smallest radii and the volume of the material used are given, two contiguous shells of different permeabilities, and three shells of different permeabilities. The main results of the investigation are that with thin shells lamination is useless, whilst with thick shells it is essential, if the best effect is desired. Experiments made on actual shells had fully confirmed the theoretical conclusions. **Prof Minchin** said the mathematical results were very simply expressed. Although the work was apparently restricted to zonal spherical harmonics, some of the important formulæ apply equally to general spherical harmonics. Referring to the difficulty of shielding by single thick shells, he pointed out that the equation giving the relation between the shielded and unshielded fields with different thicknesses of shell, represented a hyperbola with its asymptotes parallel to the axis; hence the shielding tended to a definite limit as the thickness increased indefinitely. **Mr. Evershed** said he had been engaged for the last two years on the subject of magnetic shielding, with a view to screening measuring instruments from external fields. In such cases it was not possible to use closed shells, and this introduced trouble. The best results he had yet obtained was to reduce the disturbance to about one-fifth. Another difficulty was introduced by the fact of the shield being magnetised by the current passing through the coil, and owing to hysteresis the permeability was different according as the magnetisation increased or decreased. By using an outer iron shell a great improvement had been effected. To obtain the best results it was important to have no joints in the shields. A coil frame with two shields of bent iron was exhibited. **Mr. J. Swinburne** remarked that the subject divided itself into two—shielding of instruments and shielding sources. If a dynamo itself be shielded, this did not prevent the currents in the leads producing magnetic disturbances. This was very important in ships. By using an alternator with revolving fields, all disturbances could be avoided. **Dr. C. V. Burton** enquired whether by considering the hydrodynamical analogue of a porous material the case of perforated shells could be elucidated. **Mr. A. P. Trotter** wished to know if the homogeneity of the shield was of much consequence. At Oxford it had been found that a screen of 4in. of scrap iron was better than boiler plate. **Mr. Blakesley** asked if the effect of moving a magnet sideways in a sphere had been observed. He thought the mathematics developed in the paper would be useful in working out the magnetic theory of the earth. **Prof. S. P. Thompson** thought that taking the permeability as constant would not be quite correct, for μ was a function of the magnetisation. Hence, in the cases considered, the outer shell would be the more permeable. In his reply, the **President** said scrap iron in contact was not like clear space, for there were comparatively free paths for the induction at the points of contact. As regards the shielding of the dynamo at Greenwich, Mr. Christie had written to say that the credit was due to the makers of the machine and shields, Messrs. Johnson and Phillips.

Prof G. M. Minchin, M A, read a paper on "**The Action of Electromagnetic Radiation on Films Containing Metallic Powders**." After noticing the resemblance of the phenomena exhibited by tubes containing metallic filings, shown by Mr. Croft on October 27, to those of photo-electric impulsion cells, he repeated some of the experiments with filings, and found the same effects when the filings were of ordinary fineness. He also noticed that the experiments did not succeed either when the filings were coarse or very fine. Coarse ones always conducted, whilst very fine filings or powder acting as insulation, except when strongly compressed. To establish a closer connection with the impulsion cells, he tried films of gelatine and collodion containing metallic powders. Directions for preparing the films are given in the paper. On inserting such a film in circuit with a battery, key, and galvanometer, it acts as an insulator. To render a small portion conducting, the electrodes on the surface of the film are brought very close together, and one of the wires touched with an electrified body. (An electric gaslighter was often used.) This caused a current to pass. The electrodes may then be separated a little further, and the process repeated until any desired portion is rendered conducting. The peculiarity of such a film is that, if the circuit be broken at the film, the film becomes an insulator, whereas breaking the circuit at any other point leaves the film conducting. The action of the sparks or charges on the conductivity of the films is attributed to the influence of electric surgings produced in the wires by the electric discharges. The **President** read a written communication from **Prof. O. J. Lodge**, in which the writer suggested that the phenomena of the films, and also of Lord Rayleigh's water jet experiment (in which water drops are caused to coalesce by the presence of an electrified body) were due to the range of molecular attraction being increased by electric polarisation. **Mr. Blakesley** said he had tried Mr. Croft's experiments, and found that conductivity could be established in a tube of filings whilst the circuit was unclosed. Breaking the circuit of a transformer or electromagnet would produce conductivity, hence he concluded that electric surgings were not essential. Another curious experiment was to put the discharging knobs of an electric machine on a photographic plate at a distance of a few inches. On turning the machine, a small spark travels slowly along the plate from the negative to the positive knob. On reversing the polarity of the machine, the spark travels back along the same path, but if the polarity remains unchanged a second spark usually travels along a different path. **Prof. C. V. Boys** asked Prof. Minchin whether the films themselves or the contacts between the electrode and film is made conducting by the sparks? **Prof. S. P. Thompson** wished to know if ordinary photographic dry plates would serve the purpose. **Mr. Evershed** enquired whether the metal used as electrode made any difference. **Prof. Minchin**, in his reply, maintained that the phenomena were due to electric impulses. He had not tried photographic plates, and had always used platinum for his electrodes.

LEGAL INTELLIGENCE.

HOERTER AND ANOTHER v. HANOVER CAOUTCHOUC AND TELEGRAPH WORKS.

Judgment in this case, which was referred to in our issue of the 3rd ult., was delivered on Monday in the Court of Appeal, by the Master of the Rolls, Lord Justice Lopes, and Lord Justice Kay.

The case was an appeal from the Divisional Court refusing to set aside the writ of summons and service of the notice thereof on the defendants. The plaintiffs, who carried on business in London as C. F. Mumm, brought this action for commission on the sale of goods, as agents for the defendants, who were a foreign company carrying on business at Linden, near Hanover, and for an account. By a contract in writing made at Linden, in the German language, on June 21, 1890, as modified by another contract of December 4, 1891, the defendants appointed the plaintiffs, who were described as trading as C. F. Mumm, of London, their sole agents for the sale of their goods in the United Kingdom, Canada, and the United States of America until October 1, 1892, the plaintiffs to receive a commission of 5 per cent. "upon all net amounts of invoices received after deducting freight, duty, and packing," on all sales by them of the defendants' goods. The commission was to be accounted for quarterly, and the collection of the amounts of the invoices was to be made by the defendants alone. The contract further provided that in case of disputes the plaintiffs' firm was to submit to the laws and jurisdiction in force in Hanover. On February 27, 1893, the plaintiffs issued an ordinary writ against the defendants for service within the jurisdiction, and the writ was served upon one Gilbert, on the ground that he was an officer of the defendants, who had a place of business and carried on business within the jurisdiction. The defendants entered a conditional appearance, and on March 20 the Master on the application of the defendants, set aside the service of the writ on the ground that the defendants had no place of business here, and that Gilbert was a mere agent of the defendants. On May 2 the plaintiffs applied *ex parte* to Mr. Justice Mathew, at Chambers and he gave them leave to amend the writ by making it a writ for service out of the jurisdiction, and to serve notice thereof on the defendants out of the jurisdiction, under Order 11, r. 1 (e). Notice of the amended writ was accordingly served on the defendants abroad, and they entered a conditional appearance, and applied at Chambers to set aside the writ and all subsequent proceedings. Mr. Justice Wills set aside the notice of the writ and service thereof, upon the ground that the contract provided for the determination of disputes between the parties by the Courts of Hanover. The Divisional Court discharged this order, upon the ground that there was a breach of contract within the jurisdiction—namely, non-payment of the commission, and that the clause in the contract did not give the Courts of Hanover exclusive jurisdiction. The defendants appealed.

Mr. Danckwerts, for the defendants, contended that the affidavit upon which the plaintiffs obtained leave *ex parte* from Mr. Justice Mathew did not disclose the fact that they were suing upon a contract in writing which contained the clause providing for all disputes being settled by the Courts of Hanover. This was a very material fact to be stated, and in *ex parte* applications

***uberrima fides* was necessary** (Republic of Peru v. Dreyfus Bros.). The plaintiffs, in their affidavit, stated that the greater part of the goods were sold by them in England, but that they did not know the amount of the commission due until the accounts were taken. Therefore, this was an action for an account which would have to be taken in Germany, and no commission would be due under the contract until the account was taken in Germany. Accordingly, the plaintiffs were not suing for a breach of contract within the jurisdiction. Further, if there was a breach within the jurisdiction, the Court in its discretion would not in this case, where the account must be taken in Germany and where all the books and documents were, give leave to bring the action in this country. Again, the contract contained a clause providing that all disputes should be determined by the Courts of Hanover, and the action should be brought there. Further, Mr. Justice Mathew had no power to amend the writ by converting it into a writ for service out of the jurisdiction. The proper course was to have issued a concurrent writ for service out of the jurisdiction. Lastly the notice of the writ was bad in form by omitting to state the residence of the plaintiffs and the address of their solicitors.

Mr. Temple Franks, for the plaintiffs was not called upon.

The **Court** dismissed the appeal.

The **Master of the Rolls** said that first of all it was said that the writ was a bad writ. The writ was not good for the purpose of founding the service of a notice of writ abroad, but otherwise it was a good writ. The judge was asked to amend it. Order 70 gave very wide powers of amendment. The writ being insufficient for the purpose of service abroad, the judge had power to amend it, and he turned it into a writ upon which the plaintiffs could found service of a notice of it out of the jurisdiction. It was then said that there was a want of good faith when the *ex parte* application was made to the judge for leave to amend, upon the ground that the contract was not disclosed to the judge. But supposing the plaintiffs did not consider that the particular terms of the contract affected the question, where was the want of good faith? The judge might have said that the contract would be disclosed at the proper time when it was necessary to consider it. It was said that the contract contained a clause ousting the jurisdiction of the English Courts. The clause was in a German contract, and it must be construed according to German law. Was the judge at that stage of the proceedings to try the question whether that was its effect? Was he to examine the German law and hear evidence on the point? That was not the time to discuss the contract, and, therefore, even if the contract had been disclosed, it would have had no effect upon the question before the judge. The action was really by an English firm carrying on business in London to recover commission earned. That must be a liquidated sum. The plaintiffs were to be paid commission under the contract. The ordinary rule applied—namely, that the payment was to be made in England, where the creditors were. Therefore, the breach of contract sued upon—non payment of the commission—occurred in England. Therefore, the order of Mr Justice Mathew was right, and his discretion was rightly exercised. Mr. Justice Wills set aside the notice of the writ and the service thereof on the ground that the clause in the contract provided for the determination of all disputes by the Courts of Hanover. It was impossible to say that the clause was clear, because two judges in the Divisional Court differed from Mr. Justice Wills. That being so, the right course was to allow the service of the notice of the writ to stand, and to leave the question to be argued upon a subsequent application of the defendants, or to be disposed of at the trial. As to the alleged irregularities in the notice, if they had not already been amended, they could be amended now.

The **Lords Justices** delivered judgment to the same effect.

ELECTRIC AND GENERAL CONTRACT CORPORATION v. THE THOMSON-HOUSTON ELECTRIC COMPANY.

This action was heard last week, in the Queen's Bench Division, before Mr. Justice Wills and Mr. Justice Wright.

The case raised a question as to the right to retain a large sum paid by purchasers under a contract. It was an action brought to recover the sum of £1 000 paid to the defendant company by the plaintiff company under a contract for the purchase and delivery of certain electrical machinery and plant which were to be delivered to the plaintiffs at Liverpool from the defendants' factory in America. The terms of the contract contained in letters of May last were that the defendants were to deliver at certain prices (over £6 000) the electrical machinery specified "on ship's rail at Liverpool," the goods to be shipped from America by June 13 last. The plaintiffs were to pay for the apparatus and machinery £1,000 with the order confirming the contract, and 33 per cent on the invoiced amount on delivery of bill of lading, and the rest on starting of the apparatus. **The £1,000 was sent by the plaintiffs (the purchasers) with their** confirmation of the order, and certain apparatus and material were shipped and the bill of lading sent, but the sellers stopped the goods as the 33 per cent. were not sent on delivery of the bill of lading, and the purchasers now sued for the recovery of the £1,000, which the sellers resisted on the ground that it was a deposit or "earnest," and forfeited by the breach of the contract. The plaintiffs claimed to have summary judgment under **Order 14, but there was a counter-claim by the defendants,** and an order was made at Chambers giving the defendants unconditional leave to defend, against which the plaintiffs' company appealed.

Mr Shearman appeared on their behalf, and urged that the £1,000 was not a deposit but part payment, and so, the contract *being at an end*, it ought to be paid back.

Mr. Rawlinson, on the part of the defendants' company (the sellers), argued that the £1,000 was a deposit and so forfeited by breach of the contract, and therefore not recoverable: in support of which view he cited Stroud's "Judicial Dictionary," title "deposit or earnest," which so stated the law, citing authorities in favour of that view. [**Mr Justice Wills**, however, looking at the principal case cited, said that it did not support the proposition for which it was cited, where the money was "as part payment of deposit."] This was plainly as deposit or earnest; if not, what was it? The machinery was made entirely for the purchasers—the plaintiffs—at their order, and for their purpose, and will be useless in the hands of the sellers, who cross claim for damages for the very reason that it is impossible to estimate the amount of damages, which may be largely over £1,000. Surely, therefore, it is only reasonable that the sellers should retain it; and there is at least a good defence to the action, so that the plaintiffs cannot be entitled to summary judgment.

Mr. Shearman, in reply: The words used point to part payment, not deposit—"pay for the apparatus," etc.

The learned **Judges** conferred, and

Mr Justice Wills said he came to the conclusion that the order at Chambers was right. He did not think that Order 14, providing for summary judgment, applied to cases like this, raising what might turn out to be a difficult question of law. It was never intended to throw on the judge at Chambers such a burden. It was impossible that such questions could be satisfactorily dealt with at Chambers. This very case had been so argued as to occupy about two hours, and yet no time was wasted. Such questions were not meant to be dealt with summarily at Chambers. And on that ground alone he should uphold the order, allowing leave to defend. But, on the merits, he was not satisfied that the defendants—the sellers—were not entitled to retain the £1,000. When the plaintiffs—the purchasers—renewed the bill of lading they had not remitted the amount due under the contract, and, though they had properly returned the bill of lading, the sellers might contend that they were entitled to retain the money. **He certainly was not satisfied that the defendants** were not entitled to retain the money. At all events, it was far too disputable a question to be decided summarily. To decide such cases satisfactorily at Chambers was not possible, and it only tended to put the judge at Chambers in a false position. Further, in the present case, there was a substantial counter-claim. The order, therefore, made at Chambers was right.

Mr Justice Wright was of the same opinion. It was not shown that the defendants had not from the first conceived that they had a right to retain the £1,000, making, as they did, a claim for substantial damages.

The appeal was dismissed and the order upheld.

COMPANIES' MEETINGS.

INTERNATIONAL OKONITE COMPANY, LIMITED.

An extraordinary general meeting of this Company was held on Saturday at the City Terminus Hotel, Mr. Samuel Pope, Q.C., in the chair, to consider the confirmation of the resolutions passed at the meeting on the 27th September, for changing the name of the Company to the Okonite Company, Limited, and for making certain alterations in the articles of association.

The Chairman reminded them that at the last meeting they found themselves practically at the mercy of the American shareholders, who held a preponderance of the voting power. During the discussion on that occasion objections were raised to some of the propositions which had emanated from the other side, notably one for abolishing the power of the Company to purchase its shares—a change which would affect their standing on the Stock Exchange. The resolutions were passed, but the gentleman who held the proxies of the American shareholders said he would represent to his clients the views which had been expressed by the English shareholders. A letter had since been received from America agreeing to modify the resolutions to the extent of not interfering with the existing article as to the purchase of the shares by the Company, and therefore the resolutions would now be submitted for confirmation minus that point. He held that the best thing they could now do was to agree to the resolutions.

Mr. Williams then moved the confirmation of the resolutions, with the modification referred to.

Mr. Vaughan Stevens, in seconding the motion, stated that the capital of the Company was £340,000, and that Mr. Williams had lodged proxies representing £165,490 in favour of the motion.

The **Chairman** stated that the Board held no proxies. The effect of the proposal was to transfer the management to America.

Mr. Gladstone said that the Americans, who had sold the property to them at 10 times its value, now asked that it should be placed at their entire disposal.

The **Chairman**, in reply, stated that that was no doubt the individual opinion of many of them, but he felt powerless in face of the proxies which had been lodged by Mr. Williams. The position was that the American business was making profits, which the American shareholders objected to giving up to make good the losses on the English business. At the suggestion of the American directors the works at Manchester had been closed, but possibly they might be reopened at some future time. Speaking as an ordinary shareholder, he felt that the only chance he had of getting a dividend lay in the surplus profits of the American business.

After further discussion the resolutions were confirmed.

BUSINESS NOTES.

Chesterfield.—The Town Council are seeking for powers.

St. Helens.—A provisional order is being sought by the Corporation.

Chelmsford.—Messrs. Crompton and Co., Limited, are applying for powers.

Barrow-in-Furness.—The Town Council are seeking for a provisional order.

Plymouth.—The Corporation are applying for a provisional order. So is the gas company.

Hobart Electric Tramway Company.—For the mouth of October the earnings were £1,257.

Chipping Wycombe.—An application for electric lighting powers is being made by the Corporation.

Penrith.—The Local Board, as referred to on the 10th ult., are making application for a provisional order.

Western and Brazilian Telegraph Company.—The receipts for the week ended November 24 were £3,379.

Guildford.—The Urban Sanitary Authority intend to connect the isolation hospital with the police station by telephone.

Change of Address.—The address of the Roundhay Electric Tramway is now in Roseville road, Roundhay-road, Leeds.

Oystermouth.—We shall shortly be in a position to give further information concerning the proposed electric light scheme for this town.

Crystal Palace.—The Crystal Palace District Electric Supply Company, Limited, are to ask for permission for an extension of powers.

Balham, S.W.—Mr. Peton Dashwood proposes to light his shops in Balham High-road by electricity, and to erect arc lamps close to the kerb.

Yeadon.—The Local Board are applying for a provisional order to supply electricity within the district over which they exercise authority.

Willesden.—The Local Board have decided to apply to the Board of Trade for a provisional order to light the parish by electricity.

Govan.—Messrs. Hall, Brown, Buttery, and Co., of Govan, have received an order from Dundee for a high speed engine for electric lighting purposes.

St. Asaph.—Negotiations are proceeding between a Cardiff firm and some of the leading tradesmen with a view to lighting the town by electricity.

Croydon.—A local paper states that something will have to be done in the matter of electric lighting before long in Croydon, for the electric light will come into general use.

Kensington.—The Vestry have decided not to apply to the Board of Trade for a provisional order for powers to supply the parish of St. Mary Abbotts, Kensington, with electric light.

Harrogate.—Mr. Wilkinson, the consulting engineer to the Town Council, is to report on the feasibility of using a refuse destructor for electric lighting and pumping purposes.

Buxton.—The Local Board for the urban sanitary district are applying for a provisional order under which they may produce and supply electricity within the area under their jurisdiction.

Gorseinon Electric Light Company, Limited.—This Company has been registered with a capital of £10 000 in £1 shares, to carry on business as suppliers of electricity at Gorseinon, near Swansea.

Leeds.—An electrical clock was exhibited by Mr. J. H. Gash at the Leeds Naturalists' Club conversazione on Tuesday. It was manufactured for Mr. F. W. Branson by Messrs. Gash and Skilbeck, Leeds.

Working Partner Required.—A working partner having £1,500 is required by a West-end electric lighting and engineering firm. Applications to be sent by letter to X, 19, Blackhorse road, Walthamstow, E.

Paisley.—The Police Board have under consideration the provision of one or two small sub stations, such as are provided at Aberdeen, and two or three telephone-call signal boxes, similar to those in use in Glasgow.

Dublin.—Tenders are invited, as mentioned in our last issue, by the 14th inst. for the extension of the buildings and the supply and erection of additional plant at the central station, Fleet street, Dublin, for the Corporation of Dublin.

Brazilian Submarine Telegraph Company.—The directors have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax, for the quarter ended September 30 last, and payable on the 21st inst.

Ingleton.—At a meeting of ratepayers held at Ingleton on the 16th ult., to consider the question of the introduction of the electric light in the village, Mr. T. Preece (of Messrs. Andrews and Preece, Limited) addressed the meeting on the subject.

Huddersfield.—St. George's square is the first public thoroughfare in Huddersfield to be lighted by electricity. The current was turned on for the first time on Wednesday. Three powerful arc lamps on high pillars are found ample for the illumination of the large square.

Mevagissey.—The Mevagissey Vestry on Saturday received from the Lighting Committee estimates of the cost of lighting the town with oil, gas, and electricity. The committee reported in favour of the electric light, but recommended that the matter be deferred until parish councils had been formed. The report was adopted.

City and South London Railway Company.—The receipts for the week ending November 26 were £895, against £893 for the same period last year, or an increase of £2. The total receipts for the second half year of 1893 show an increase of £183 over those for the corresponding period of 1892.

J. Defries and Sons, Limited.—This Company has been registered with a capital of £100,000 in £100 shares. The object is to acquire the business of illuminating and decorating contractors, chandelier manufacturers, gas and electrical engineers, etc. hitherto carried on by J. Defries and Sons, at 147, Houndsditch, Gravel lane, London.

Coventry.—The Electric Light Committee of the Town Council have been instructed to draw up a list of instructions for their management. The following gives the names of the members of the committee: The Mayor; Aldermen Tomson, Hill, and Gulson; Councillors Fowler, Goate, Starley, West, Morton, Hughes, Thomas, James, Wormell, and Liggins.

Reading.—The temporary electric lighting of the Reading Town Hall, on the occasion of the visit of H.R.H. Princess Christian to open a bazaar there on the 23rd and 24th ult., was carried out by Messrs. T. C. Williams and Sons, electrical engineers, of Reading, by means of 17 high candle-power incandescent lamps, the current for which was supplied by the Reading Electric Supply Company.

Belfast.—The electric lighting of Queen's Quay, which was referred to in our last issue, was inaugurated on Friday in the presence of Mr. Giles, engineer to the Harbour Commissioners; Mr. George Combe, consulting electrical engineer for the contract; and Messrs. Siemens Bros.' representative. One circuit, comprising half the lamps of the entire number erected, was connected up to the machines. The other circuit is being thoroughly tested.

Cheltenham.—Major-General Babbage has addressed a letter to Colonel Hasted in connection with the latter's enquiry into the application of the Town Council for a loan for electric lighting. The Major submits that the time is not opportune for such an undertaking while urgent matters, such as preventing sewer inundations in basements of houses, procuring an adequate water supply, and other wants, exist far more urgent than electric lighting.

Greenock.—Tenders are invited for fitting a wooden steam yacht of 60 tons with electric light as follows: 20 4-c.p. incandescent lamps about cabins and saloons, two masthead lamps of 210 c.p. each, with wires; dynamo and engine of sufficient power to run all lamps at the same time. Tenders will also be considered for a second hand complete apparatus. Applications to be sent to Messrs. J. and H. M. Paterson, 32, Eldon street, Greenock.

Gas Traction Company, Limited.—This Company has been registered with a capital of £100,000 in £1 shares. The object is to acquire patents and inventions relating to the propulsion of vehicles by means of gas, and the construction and working of cars, and as suppliers of electricity, manufacturers of all kinds of machinery and apparatus connected with the generation, storage, compression, supply, application and distribution of gas and electricity.

Aberdare.—As stated in our last issue, an application is to be made to the Board of Trade for the issue of a provisional order to Messrs. J. C. Howell and Co., Limited, to enable them to supply the electric light in Aberdare within a radius of half a mile of St. Elvan's Church. The gas company have hitherto kept up the price to 4s. 3d. per 1,000ft., but now that the above-mentioned company are applying for parliamentary powers to employ electric light, the directors announce a reduction of 3d. per 1,000ft.

Wigan.—At a meeting of the Gas Committee last week a letter was read from the Corlett Electrical Engineering Company enclosing a list of persons who are willing to adopt the electric light if the Corporation will supply it at the same prices as other corporations. It was decided that the chairman, vice-chairman, Messrs. Jno. Johnson, Richards, Smith, and Rigby be appointed an electric lighting sub-committee, and that the above communication be referred to the sub-committee for report at the next meeting.

Kingston-on-Thames.—The Improvement, Property, and Sanitary Committee of the Town Council have agreed to consider the question of the means for the prevention of fire in the borough. Several questions were asked last week at a meeting of the Council by members as to the lighting of the public lamps. Councillor Baker stated that a few mornings since the lights were put out early, before it was light. Councillor Collings said that orders had been given for the lamps to be lit at sunset, and to be kept alight till seven in the morning.

Monmouth.—An enquiry has been held by Mr. Thos. Codrington, M.Inst.C.E., regarding a proposed loan of £18,000 for carrying out a complete scheme of drainage and electric lighting for the borough. Mr. C. W. Lailey, and Mr. R. A. Dawbarn, of the Brush Electrical Company, explained their plans. Some slight modifications were directed to be made in the scheme, and the Mayor promised that the drainage should be commenced at the earliest possible moment, the provisional order for electric lighting to be applied for in the meantime.

Jedburgh.—Preparations have been proceeding for the introduction of the electric light at Hartrigge House, the residence of Lord Stratheden and Campbell. A pond capable of holding 100,000 cubic feet of water has been made at the Tower Burn,

and from this pond the water is carried along a lade to a turbine, developing 20 h.p. Accumulators are also used. There are 140 lights for the house, 15 for the stables, and five for the laundry, making a total of 160. An electric motor is arranged in the stable yard for working small machinery.

Falmouth. Dr. Banks presented last week at a meeting of the Urban Sanitary Authority the report of the Lighting Committee, which recommended the payment of £8 to Messrs. Beale and Co. for their report upon the electric lighting scheme. In referring to some applications for more lamps he said the committee were averse to tinkering with the subject, but would like to have instructions for the preparation of a comprehensive scheme for the adequate lighting of the town by gas, electricity, or otherwise. The report was adopted, but no further steps were taken in the matter.

St. Pancras.—The St. Pancras Vestry invite tenders for excavating and constructing an underground water tank in connection with the electric lighting and refuse destructor station in King's-road, Camden Town, N.W. The drawings can be seen at the offices of Prof. H. Robinson, C.E., 13, Victoria-street, S.W., where a copy of the general conditions, specification, and schedules of quantities can be obtained on payment of five shillings, which will not be returned. Tenders to be sent in to Mr. Albert E. Pycraft, chief clerk, Electricity and Public Lighting Department, Vestry Hall, Pancras-road, N.W., endorsed "Tender for Water tank," before 12 noon on Friday, 8th December.

Belfast and Newtownards.—An adjourned meeting of committee has been held at Newtownards to consider improved railway communication between Belfast and Newtownards. Some correspondence, which had been elicited on a number of matters in connection with the scheme, was read, after which a sub-committee, who had been appointed for the purpose, presented a report on an interview they had had with Mr. Nance, manager Belfast Tramway Company, which stated that Mr. Nance recommended electricity as the best motive power. It being too late for parliamentary notices to be served for next session, the committee was continued to report on various matters in connection with the scheme.

Belfast.—The Corporation invite tenders for the following works in connection with their electric lighting station in Chapel-lane, Belfast: (1) Gas engines and dynamos, (2) switchboard and connections, (3) batteries, (4) laying of concrete culverts, (5) cast-iron work, (6) insulators, (7) insulated cable, (8) copper strip. Copies of any of the specifications can be obtained from Mr. S. Black, the town clerk, or from Prof. A. B. W. Kennedy, at his office, 19, Little Queen-street, Westminster, S.W. Firms wishing to obtain copies of any specifications must send with their application a deposit of one guinea for one specification or two guineas for any larger number; the deposit will be returned on receipt of *bona fide* tenders. Tenders are to be directed to the town clerk by the 15th inst.

Shepton Mallet.—The works of the Anglo-Bavarian Brewery Company are lighted with arc lamps on the Thomson-Houston system. The dynamo is situated near the fire brigade station, and is driven by a 60-h.p. engine. An interesting application of electricity has been successfully made as a motive power. The refrigerators used in the works involve a large consumption of water, and a spring has recently been acquired about half a mile from the works. Steam pumping would require an engine house at the spring, with the expense of keeping a man on the spot and of hauling coal across the fields to supply the furnace. By the use of electricity instead, the motive power can be supplied from the brewery itself, where the pumps can be started or stopped as required by merely turning a switch, and it is only necessary to visit the spring once or twice a day for the purpose of inspection.

Lighting at Halifax.—The Corporation, owing to the destruction by fire of the electric lighting works in Square-road, are pushing on their own electric lighting scheme with all speed. They have accepted tenders for the works required at the central establishment in Cripplegate. The engines are to be supplied by Messrs. Pollit and Wigzell, Sowerby Bridge; the boilers by Messrs. Yates and Thom, Blackburn; and the mains by Messrs. Siemens and Co. A project is about to be carried out to test the feasibility of generating steam for electric lighting and similar purposes with ashbin refuse as the only fuel. The power is obtained from Livet's expanding flue steam generators, capable of exerting 200 h.p. when town's refuse is burned. An electrical installation is being put down which will consist of a powerful turbo-electric generator, supplying a projector search-light of 25,000 c.p., and a full complement of arc lamps.

Southampton.—The Works Committee of the Harbour Board reported at a meeting last week that the sub-committee stated that on the 26th October they witnessed the lifting and slewing of the electric crane with a weight of three tons in the slings, and afterwards the crane was put through severe tests, both as to speed and weight, and both lifting and slewing. All the tests required by the specification were carried out in a satisfactory manner, the speed being in excess of that specified. A report was also received on the subject from Mr. Aldridge, with a table of results. Alderman Cleveland expressed his great pleasure at hearing so satisfactory a report of the electric cranes, in which he had taken so great an interest, and had determined to look after the Harbour Board on the matter. He hoped the second crane would achieve an equal success, and then they would have appliances which, as far as his knowledge went, were not possessed by any other port in the kingdom.

The Royal Exchange.—The Lord Mayor (Mr. Alderman Tyler), as stated in our last issue, performed the ceremony on the 23rd ult. of turning on the current in connection with the installation of the electric light at the Royal Exchange. There are four arc lamps in the quadrangle, each of 2,500 c.p., and an incandescent lamp of 100 c.p. in each of the four corners of the ambulatory. The current is supplied by the City of London Electric Lighting Company, Limited. In consequence of the building being washed down periodically by the fire hose the cables attached to the mains have been specially made concentric and lead covered, and all the joints are enclosed in cast-iron boxes filled in with hot bitumen. This is the first time that the interior of the Royal Exchange has ever been illuminated with artificial light, although great inconvenience has hitherto been experienced in foggy weather as a consequence. The installation has been carried out from plans and specifications prepared by Messrs. Shepherd and Watney, Leeds, the contractors being Messrs. J. G. Statter and Co.

Lighting at Islington.—The Special Electric Lighting Committee reported at a meeting of the Vestry last week that they had made enquiries for a site for the proposed electric lighting works. The committee thought that the Great Northern Railway Company's property in Eden-grove and Burnand-place would be suitable for the station. The land which the company were willing to sell covers an area of about 32,400 square feet. The committee were advised by the electrical engineer that three cartway entrances would be obtainable to the site, one from Eden-grove, one from Burnand-place, and one from Wellington-road; that engine rooms could be erected thereon capable of containing at least 11 sets of plant for incandescent lighting (allowing full room for slow-speed horizontal engines), and six sets for arc lighting; that ample accommodation would be available for offices, switch-room, workshops, coal stores, etc.; and that easy means of obtaining coal direct from trucks into the works could be secured. The committee recommended the Vestry to refer it to them to carry out the negotiations for the purchase of the site. The Vestry adopted the report of the committee.

Barnet.—The Electric Lighting Committee of the Local Board mentioned, at a meeting on the 15th ult., that it was of opinion, provided the electric light could be supplied by a company upon a satisfactory basis to the Board, or could be supplied by the Board upon a satisfactory commercial basis, that the town should be lighted by electricity. The committee further recommended, at a later meeting, that an advertisement should be inserted in the *Electrical Engineer* and another paper as follows: "The Barnet Local Board invite applications from companies or firms willing to take the transfer and to undertake and carry out the Board's guarantee by the Barnet Electric Lighting Act, 1893. Applicants are requested to state: (1) The system of lighting proposed, (2) the charge for lighting the public lamps, (3) the terms upon which and at what periods they would give the Local Authority the option of repurchasing the undertaking." This report was adopted. The advertisement was published in our last issue, and is also printed in the present number. The clerk was instructed to write to the Electric Installation Company, who had sent its men there, and acquaint them with what the Board proposed to do.

Lighting at Guildford.—We referred last week to a public meeting held to consider the introduction of electric light. At that meeting, it will be remembered, a considerable amount of support was offered, and a committee was appointed to make further enquiries and ascertain whether the amount required for the initiatory proceedings could be raised within the specified time during which a provisional order could be applied for. The committee, which was fully representative, decided that if £300 were subscribed in the way of "founders' shares" within the limit of the borough the order should be applied for in the usual way. This condition has been complied with, and formal notice to the Board of Trade has been given. The provisional order is asked to authorise the Holloway Electricity Supply Company, Limited, to supply electricity for public and private purposes within the borough of Guildford, in the event of a company being formed, but the Holloway Company will hand over their powers to the local one when the latter is ultimately constituted. There is great unanimity in Guildford as to the desirability of introducing a supply of electricity into the borough. If the Corporation can have inserted in the order a reasonable clause enabling them at some future time to buy up the company, no opposition may be expected from that quarter.

The Sunderland Tenders.—The sub-committee are now considering tenders for the station. Eight contracts are to be made for the laying out of the necessary plant, and the tenders sent in have puzzled the sub-committee which has the work in hand. There were 28 for Lancashire boilers, the prices ranging from £2,500 to £1,235. Contract No. 2 is for compound engines and dynamos, for which 16 tenders had been sent in, the figures ranging from £6,015 to £4,040. For motors, alternators, and switchboards there were 15 tenders, the highest being £3,000 and the lowest £1,100. No. 4 specification was for main switchboards, instruments, and connections. Here there were 19 tenders, varying in price from £1,350 to £575. For batteries there were seven tenders, the highest being £2,280 and the lowest £763. For insulated cables there were seven tenders, and for roadwork 15 tenders, but the total prices were to be ascertained on measurement. The eighth and last specification was for copper strip, and 11 tenders were sent in, the price per pound being 7½d. in the case of the highest and 6¾d. the lowest. One firm—Messrs. Parsons and Co., of Newcastle-on-Tyne—tendered to do the whole of the work on a system of their own for £19,044. The great diversity of prices so bewildered the committee that they decided to send the tenders to Prof. Kennedy to go through them and report on the matter.

Lighting at Bolton.—A lecture on "Bolton's Electric Supply" was delivered last week at the Technical School by Mr. J. H. Rider, M.I.E.E., electrical engineer to the borough. The chair was occupied by Alderman Miles, J.P., chairman of the Gas and Electricity Committee of the Corporation. The Chairman, after paying a compliment to the abilities of Mr. Rider, said the Gas Committee had determined that they would spare neither pains nor expense to have a first class installation for the town. Mr. Rider then delivered his lecture. He explained the direct and alternating current systems, and gave illustrations of the advantages of incandescent lamps. He also explained and practically illustrated the principle of the arc light. With regard to the cost of the illuminant, he said that many people did not seem to understand the list of charges sent out by the Corporation. They proposed to charge for the light by the indications of a meter similar in appearance to an ordinary gas meter, but instead of charging so much per cubic foot, they would charge so much per Board of Trade unit. There would be a differential system of charging. The proposed sliding scale of charges ranged from 5½d. to 8d. per unit, the idea being to give rich and poor consumers an equal chance of obtaining the light. A vote of thanks was passed to the lecturer, and also to the Chairman, who said it was hoped in a few months that the installation would be completed.

Derry.—The project undertaken by the Corporation for the street illumination of Derry with the electric light is now nearing completion. It is understood that, unless some unforeseen circumstance occurs to interfere with present progress, the promoters are confident that the greater portion of the city will be electrically lighted before Christmas. The new generating station buildings are situated between Strand road and the Quay. One engine has been already put in position, and the makers state that in less than a fortnight they will be able to test it under steam. This engine is capable of working up to 140 h.p. The flywheel is 8ft. in diameter, driving two dynamos by belts. Only one third of the area of the yard at the station is occupied by the buildings for the street lighting, the remainder being reserved for the house to house lighting scheme should the citizens express a desire to take it up. The machinery room is 60ft. long by 40ft. wide, open to the ridge a clear height of 32ft. Thirteen feet above the floor level runs an overhead travelling crane for lifting any part of the machinery. The boiler house is built to contain two Lancashire boilers, each 26ft. long and 7ft. in diameter, and each capable of generating steam for 200 h.p. with average coal and draught. At the back of the boiler is fixed a Green fuel economiser, consisting of 96 pipes, through which the water is passed before entering the boilers. The chimney stack is 125ft. high. The dynamos are ready for delivery, but it is not considered desirable to have them on the spot until the engine and flooring are complete. The cables are now completed in two circuits. There are in all 17 miles of cables already laid in the city and Waterside. A start has been made on the west section. Over 100 street pillars have been erected in the various thoroughfares, and the lamp carriers, ready for the lamps, have been fixed on most of them. A number of the lamps are already on the spot complete for erection upon the pillars. All the electrical work in connection with the scheme is being carried out by Messrs. Siemens Bros. and Co., Limited, under the personal supervision of their engineer, Mr. W. A. Collings. The lamp pillars are being supplied and all mechanical work satisfactorily performed by Messrs. Alex. Brown and Son, Derry. The contract for the station buildings, chimney, boiler setting, foundations, etc., is in the hands of Messrs. Matthew M'Clelland and Co. The designs have been furnished by Mr. R. Eccles Buchanan, C.E., architect, Shipquay street; while Mr. H. W. Blake watches the interests of the Corporation as their consulting engineer.

Dundee.—A representative of a Dundee paper has had an interview with Mr. Matthew Buchan, who has just returned from America, where he has been engaged as an electrical engineer and tramway expert with the chief electrical companies in the United States. Mr. Buchan is a native of Portobello. Previous to going to America, he had five years' experience in England. During the five years he was in the States he was connected with the Westinghouse, the Edison, and latterly with the Thomson Houston Companies. He studied electricity as a motive and lighting power, and he has now resolved to remain in this country and establish himself as an electrical engineer. Mr. Buchan said that if electricity were supplied to the houses it could be utilised as a motor for domestic purposes. In Dundee there were many persons who would utilise it in that way if it could only be supplied at a cheaper rate. The central station could easily supply electricity for such purposes if the consumers would take it during the day, as they had a number of machines standing idle all day. If that were done, motors could be supplied by the company which would drive sewing machines and other domestic machines. In America this system of utilising electricity is being rapidly developed. With regard to tramways, the speaker stated that a gradient of about 10 per cent. could fairly be worked, if it was not necessary to stop on the incline. He preferred the overhead wires to the underground conduit system. Asked whether there was any danger from the overhead wire breaking, he stated that such accidents rarely occurred. In America it was the general rule to run at a potential of 500 volts, but that could be reduced for safety to 400 volts. A shock of 500 volts might almost kill a man, but it did not do it as a rule. At 400 volts there was no danger to human life. The danger would thus be very small. The objection to the underground conduit system was the trouble caused by the conduit in which the wire is laid being filled with dirt and dust. When heavy rain fell the conduit was apt to be flooded. Wet lessened the power of the electric current, and if the channel was flooded the traffic would be interrupted till it was cleared. The lines at present in existence in Dundee would be suitable for electric cars. The electric cars would be a great saving of horses, and they could do away with the unsightly and dangerous steam cars. The cars generally ran in America at a speed of about six or seven miles an hour in the city, but when they got into the suburbs where they had a clear country he had seen them spinning along at the rate of 20 miles. Mr. Buchan could not speak positively regarding the financial results of the electric system in America. One company he knew paid a dividend the first year, and one thing was certain, if they did not pay the Americans would not be extending them all over the country.

Lighting of Harrow.—As stated in our last issue, the Local Board are applying for a provisional order. Before this decision was arrived at, the matter was fully discussed by the members of the Board. At a recent meeting the Chairman called attention to a piece of land near Harrow Pond which had been acquired. At the time of the purchase it was thought to erect an electric light station, but there was then no thought of public baths. Mr. Pitcairn presented the report of the committee appointed to deal with the subject. The report stated that the committee, in accordance with the authority given them to employ an electrical engineer, instructed Mr. W. C. C. Hawtayne, of 3, Princes'-mansions, Victoria street, S.W., to furnish them with a report, and at the same time the clerk put himself into communication with the school authorities with a view to ascertaining whether the light would be adopted by the masters and in the school buildings. Mr. Hawtayne had sent in his report, in which he dealt fully with the subject, and basing his figures on the assumption that all the public lamps in the district would be lit, that the light would be taken by the masters in their houses and in the school buildings, and that 1,000 lamps would be taken by other private consumers in the compulsory area suggested by him, Mr. Hawtayne advised the committee that if the light was supplied at 8d. per Board of Trade unit the experiment might be expected to result in a surplus of revenue over expenditure of £150. The best site for the station was considered by Mr. Hawtayne to be land adjoining the depôt of the Metropolitan Railway Station at Pinner-road, as coal could be cheaply delivered there, but it was not available for purchase. It had occurred to the committee and to Mr. Hawtayne that Harrow Pond was from its central position a most convenient site, and here he proposed that the station should be established. Another reason for choosing Harrow Pond as a site was the question of public baths. There had of late been a feeling that public baths were desirable. The report stated that if it could be shown that public baths could be established and maintained at a reasonable cost, the committee thought no more suitable place could be found than at Harrow Pond, and if they were constructed in conjunction with an electricity supply station a great saving would be effected in the cost of the original construction, and still more in the annual cost of each undertaking. Mr. Hawtayne estimated that the annual saving in the case of the electricity supply station in conjunction with public baths would be a further £150. The committee therefore suggested that if the Board desire to proceed with the electrical work, plans should be obtained which would make it possible to erect the station either in conjunction with public baths or to admit of public baths being added hereafter. The committee stated that if the Board did not take up the question of the electric light it would be possible for Messrs. Joel and Co., who had already given notice of their intention to apply for a provisional order, to obtain it. The committee did not think it would be advisable to give them this opportunity, but were strongly of opinion that if there are reasonable prospects of a profit being made by electric lighting, the Board should secure these advantages for the ratepayers, and keep as far as possible the control of the streets. The committee recommended that a fee of £25 should be paid to Mr. Hawtayne in respect of his enquiries and report; that it be left to the committee to offer a premium of £25 to architects for the best plans for an electricity supply station, in conjunction with public baths, to be constructed upon the Harrow Pond and Gardens site, and that a provisional order should be applied for. These recommendations, as already mentioned, have been adopted.

Elmore's French Patent Copper Depositing Company, Limited.—Under a winding up order granted on July 8 against this Company, a statement of affairs has been submitted by the secretary and is concurred in by Major Jones and Sir J. D. Mackenzie, the directors. The gross liabilities of the Company are returned at £140,460, of which £53,458 are expected to rank, and there do not appear to be any assets available for the unsecured creditors. As regards contributories, the total deficiency is £298,290. From the observations of the official receiver and provisional liquidator (Mr. C. J. Stewart) it appears that the Company was incorporated on September 10, 1890, and was formed for the purpose of acquiring and working in France certain French patents relating to process for manufacturing copper articles discovered by Messrs. F. E. and A. S. Elmore and patented by them in 1885. In 1889 a company was formed to acquire and work their patents relating to Great Britain and Ireland. The official receiver states that at the date of the formation of the Company, Elmore's Foreign and Colonial Patent Copper Depositing Company, Limited, were the owners of all the existing patents for other parts of the world relating to the Elmore copper process. On September 4, 1890, the Foreign and Colonial Company agreed with Woodhouse and Rawson United, Limited, now in liquidation, that the latter should form a company for the purpose of acquiring the patents for France relating to the same process in consideration of £15,000 in cash and certain premiums. The benefit of this agreement was transferred by Woodhouse and Rawson

United, Limited, on September 9, 1890, to the Phœnix Trust, Limited, which company appears to have actually promoted the French Elmore Company, Limited. On the following day the French Elmore Company agreed to purchase from the Foreign and Colonial Company the French patents above mentioned for the sum of £83,500 in cash, £66,500 in fully paid-up shares, and a premium of 10s on each share subscribed for by the public. This agreement was duly carried out, the purchase price paid to the vendor company being £66,500 in shares and £116,875 in cash. A prospectus was issued to the public in September, 1890, containing extracts from various reports speaking in favourable terms of the Elmore copper process, and the whole of the original capital of £66,750 offered to the public was at once subscribed for and allotted. It was also pointed out that, after payment of the purchase money to the vendor company, the sum of £30,000 would be left for working capital. On October 1, 1890, M. Secrétan was appointed manager of the company in France, and shortly afterwards a committee was appointed to act with him. In November, 1890, the Board resolved that it was advisable to erect works in the North of France on a much larger scale than had been contemplated at Bellegarde, and in the following month it was decided that 37 acres of land at Dives, near Havre, should be acquired for that purpose. The official receiver after giving some further details as to the operations of the Company, states that the whole of its monetary resources were exhausted in connection with the establishment of the works in France, and it was unable to pay the interest falling due upon the debenture stock on November 1, 1892. Under the powers contained in the debentures Mr. J. H. Duncan was appointed receiver on behalf of the holders. The Company being unable to continue its business, the shareholders subsequently resolved that it should be wound up voluntarily. Mr. F. W. Pixley being appointed liquidator. The official receiver avers that no dividends have been paid on the ordinary shares, but a dividend of 10 per cent. on the preference shares, which was guaranteed for one year by the Foreign and Colonial Company, appears to have been paid by that company. The failure of the Company is attributed by the secretary to the fact that the works were undertaken on too large a scale in proportion to the capital. It was intended to raise more capital later when the merits of the Elmore copper process had been proved, but this had not been done by the time the additional capital was required, and consequently the preferential shares were not subscribed for to the extent that had been hoped.

PROVISIONAL PATENTS, 1893.

NOVEMBER 20.

22140. **Improvements in incandescent electric lamps.** William Shaw Smith, 20, Tanfield chambers, Bradford.

22184. **Regulating apparatus for electromotors.** Charles Denton Abel, 28, Southampton buildings, Chancery lane, London. (Berliner Maschinenbau Aktien Gesellschaft vorm. L. Schwartzkopff, Germany.)

22186. **Improvements in lock and block electric apparatus.** Edward Tyer, 28, Southampton buildings, Chancery lane, London.

22195. **An improved permanent magnet.** Arthur Thomas Collier, 11, Southampton buildings, Chancery lane, London.

22214. **Improvements in glass bulbs relating to incandescent and other lighting.** George William Pridmore and Thomas John Sturgeon, 2, Broad street buildings, Liverpool street, London.

NOVEMBER 21.

22253. **Automatic railway electric signals.** Charles Hamlin Bradrick and Burton Aldest Karr, 154, St. Vincent street, Glasgow. (Complete specification.)

22255. **Improvements in signal telegraphy.** Hugh Donald Fitzpatrick, 70, Wellington street, Glasgow. (The Boughton Telephotos Company, United States.) (Complete specification.)

22274. **Improvements in primary electric batteries.** Alfred Vincent Newton, 6, Bream's buildings, Chancery lane, London. (Alfred Nobel, France.)

22304. **Improvements in or connected with trolleys for electric railways.** James Trezevant Fuller, Norfolk House, Norfolk street, Strand, London.

22311. **Improvements relating to storage batteries.** Edward Preston Usher, 45, Southampton buildings, Chancery lane, London. (Complete specification.)

22312. **Improvements in storage batteries.** Edward Preston Usher, 45, Southampton buildings, Chancery lane, London. (Complete specification.)

NOVEMBER 22.

22335. **The electrical and explosive method for extinguishing fires.** John Worthington and Robert Parkinson, Post Office-chambers, Coronation street, Blackpool.

22359. **An improved electrical detachable joint.** Frederick King and William Phillips Mendham. The Western Electrical Works, Narrow Wine street, Bristol.

22363. **An improved multiple-circuit microphonic transmitter.** Frederick Thomas Trouton, Caerleon, Killiney, co. Dublin.

22366. **Improvements in phonographs.** William Henry Dunkley, 79, Jamaica row, Birmingham.

22379. **Improvements in charging primary batteries.** Samuel Miller and Charles James Grist, 1, Langton-cottages, Melbourne square, Brixton, London.

22395. **Improvements in electric systems and apparatus.** Percy Edward Pownall and Robert Bolger Pownall, 55, Chancery lane, London.

NOVEMBER 23.

22437. **An improved electrical measuring instrument.** Francis Henry Nalder, Herbert Nalder, Charles William Scott Crawley and Alfred Soames, 16, Red Lion street, Clerkenwell, London.

22438. **Improvements in pivoted electrical measuring instruments.** Francis Henry Nalder, Herbert Nalder, Charles William Scott Crawley and Alfred Soames, 16, Red Lion-street, Clerkenwell, London.

22439. **Improvements in electrical measuring instruments.** Francis Henry Nalder, Herbert Nalder, Charles William Scott Crawley, and Alfred Soames, 16, Red Lion street, Clerkenwell, London.

NOVEMBER 24.

22519. **Improvements in clips for electric conductor casing.** Charles Darrah, of the firm of Baxendale and Co., and Charles Cartwright Metcalfe, 70, Market street, Manchester.

22562. **Improvements in or connected with electrical signalling apparatus.** Thomas Davis and Edward Davis, 6, Lord-street, Liverpool.

22570. **Improved apparatus for working railway switches by means of electrical energy and for signalling in connection therewith.** Siemens Bros. and Co., Limited, 28, Southampton buildings, Chancery lane, London. (Messrs. Siemens and Halske, Germany.)

22584. **Improvements in means for fixing fuses in electric circuits.** Richard Ernest Holdom and Herbert Smyth, 37, Chancery-lane, London.

NOVEMBER 25.

22594. **Improvements in arc electric lamps.** William James Davy, 161, Huddleston road, Tufnell-park, London. (Complete specification.)

22651. **Improvements in electric lamps and shade holders.** Leon Thomas Buckler and Thomas Clarke, 6, Lord-street, Liverpool.

22674. **Improvements in or relating to electric regenerative batteries or accumulators and in porous cells therefor.** Reginald Haddan, 18, Buckingham street, Strand, London. (Henry Riguelle, Belgium.)

SPECIFICATIONS PUBLISHED.

1887.

NOTES.

Bills.—No less than 27 electric lighting Bills are being promoted for the next session.

Hammersmith.—It is intended to light with both gas and electricity the new town hall to be built at Hammersmith.

No Gas Wanted.—The City Commissioners of Sewers decided on Tuesday to remove the gas standards in the City streets.

Long-Distance Telephony.—The telephonic service between Denmark and Sweden was formally inaugurated on Tuesday by King Christian and King Oscar.

Bristol.—The central station is now in operation, current being supplied to both public lamps and private customers. Application has been received for 14,000 lamps.

The "Medical Battery" Company, Limited.—The hearing of the charges against the officials of this company was resumed on Tuesday and Wednesday and was again adjourned.

The Gas Met him Half-Way. — A Carlisle man found a leakage of gas, in the usual manner, a few days ago by applying a light. There is no such danger with the electric light.

Rising in the Main.—Not only is gas rising in the main, but also in price in different towns. This fact is having a tendency to bring the electric light more prominently forward.

St. Paul's Cathedral to be Lighted.—The Restoration Committee of St. Paul's appointed a sub committee on Tuesday, to enquire as to the cost of introducing the electric light into the cathedral.

Board of Trade Rules.—We understand that a meeting of those members of the Electrical Section of the London Chamber of Commerce interested in these rules will be held at the offices of the Chamber of Commerce to-day.

International Exhibition.—The mayors of the leading boroughs have received a circular stating that a committee has been formed to promote a scheme for holding in London during 1896 or 1897 an international exhibition on a large scale.

Society of Arts.—On Monday the third Cantor lecture on "The Art of Book and Newspaper Illustration," by Mr. Henry Blackburn, will be delivered. On Wednesday a paper will be read by Mr Lewis H. Isaacs on "Carriage-way Pavements for Large Cities."

Traction at Poole.—As mentioned in our issue of the 17th ult., a scheme is being promoted for the construction of an electric tramway between Poole and Bournemouth, and for the purpose of utilising the supply station for furnishing electric light in the neighbourhood.

Train-Lighting.—The penny-in-the-slot system was introduced on Sunday in a train on the Richmond branch of the District Railway. In each carriage are four electric lamps, which can be turned on when a passenger puts a penny in the slot. The light burns for 30 minutes.

Traction at Llandudno.—As mentioned in a previous issue, it is proposed to construct an electric railway up the Great Orme's Head. Last week, under the auspices of the Llandudno Literary Society, a public discussion took place on the project, and a resolution in favour of it was carried.

The Institution.—It may be as well to remind our readers that the annual general meeting, as mentioned last week, will take place on Thursday next. After the ordinary business has been disposed of, the paper on "The Electrical Transmission of Power from Niagara Falls" will be further discussed.

Why Automatic Meters were Adopted.—A correspondent suggests that the fact that the electric light has become so much in vogue in large establishments has doubtless induced the Liverpool Gas Company to adopt the automatic meter system with the object of retrieving some of the lost consumption.

Lightning Expresses Unbearable. — It appears that the physical strain upon the drivers and stokers of high-speed trains in the United States is so considerable as to tell very severely upon the health of the men. This seems to be another point adverse to the lightning express railway service proposed by Mr. Behr.

New Book.—Signor Guido Castagneris has written a work upon "Electric Railways and Tramways," which is just published from the offices of our contemporary *L'Elettricita*. Under the exact title of "Tramvie e Ferrovie elettriche," this book contains 430 pages and some 200 illustrations, but nothing very new in the way of substance.

Switches and Switchboards.—We have received a copy of the price-list of switches, switchboards, and fuse-boards issued by Munro's Electrical Manufacturing Company, Limited, of 9, Holland-place, Glasgow. The company have supplied complete switch and fuse boards, among others, to various corporations, railway companies, colleges, etc.

Electric Lighting.—Mr. E. Eugene-Brown, M.I.E.E., of Messrs. J. H. Holmes and Co., read a paper on "Electric Lighting," before the Northern Architectural Association, on the 29th ult. The author described the various systems of electric lighting, explained the work and measurement of currents, and exhibited lamps, sections of cables, electric light fittings, etc.

Those Loving "Couples."—The sub-editors—no! assistant-editors—of all our electrical contemporaries are on the war-path. In their issues of the 1st inst. our contemporaries write of "installation couples." It would be interesting to learn whether they were single or married. If the latter, a good "installation couple" (insulated cable) might occasionally come in handy.

The Engines were not Detrimental.—The award has been made by Mr. H. T. Steward in the arbitration in connection with the alleged damage to the Monte Carlo Hotel, Leicester-street, by the electric lighting engines of the Empire Theatre. Damages to the extent of £2,000 were claimed, but the award is in favour of the Palace Company, M. Guffanti, the claimant, having to pay all costs.

Magnetic Counter-Thrust Bearing.—The name of Tesla goes of course a long way in fathering or fostering a proposal, and hence some notice may be taken of an idea said to have received the approval of that well-known scientist. There is no doubt some amount of power-loss incurred by the use of ordinary thrust bearings employed on ship screw-shafts; but whether this end thrust can be satisfactorily overcome by a magnetic pull in the opposite direction is, to say the least of it, undecided from actual results.

City and Guilds of London Institute.—Sir R. Webster, Q.C., M.P., presented at the Goldsmiths' Hall on Wednesday evening the prizes and certificates awarded in connection with this institution. The Lord Mayor presided, and amongst those present were Sir W. Prideau, Prof. W. C. Unwin, Prof. Silvanus P. Thompson, Mr. J. C. L. Sparkes, Sir Philip Magnus, Mr. C. W. B. Burdett,

Sir F. Bramwell, Mr. E. L. Beckwith, Mr. George Baker, Mr. J. Diggle, Sir F. Abel, Mr. W. Bousfield, and Mr. Alderman and Sheriff Moore.

Students of the Institution.—A meeting of the students of the Institution of Electrical Engineers will take place on Friday, the 15th inst., at 8 o'clock, at 28, Victoria-street, Westminster. A paper on "The Brightness of Light: its Nature and Measurement," by Messrs. J. M Barr and C. E. S. Phillips, will be read, and a letter concerning the premium offered to students by the Institution will also be presented.

Hampstead-Charing Cross Railway.—The Bill promoted by the Charing Cross, Euston, and Hampstead Railway Company, referred to in our last issue, is to authorise the compulsory purchase of additional lands in connection with the Company's authorised stations, subway for foot-passengers, and works; or for new station or stations, or subways for foot-passengers; easements under roads; provisions as to sale of surplus lands; exemption from operation of Section 92 of the Lands Clauses Consolidation Act, 1845; amendment of Company's Acts, etc.

Telephony in Germany.—It appears that the number of telephone stations in Germany, which was only 1,504 in 1881, had increased at the beginning of this year to 63,558, of which Berlin had no fewer than 17,424, with over 20,400 miles of lines. The inter-urban telephonic service is also increasing very rapidly, and there were at the beginning of the year 310 long-distance telephones, with 14,280 miles of lines, the longest direct line being that between Berlin and Breslau, which is nearly 200 miles. Since then the Cologne-Berlin line, 293 miles long, has been put into service.

Writing on Trees with Search-Lights.—A demonstration was given on Saturday at the Cardiff Town Hall to test the utility of search-lights in connection with sign-writing. Captain Ronald Scott, M.I.E.E., supplied the machinery and conducted the experiments. The current was generated by means of a dynamo worked at the rear of the Town Hall. Taking alternately for a background the highest buildings in the vicinity, trees, and steam, by means of slides after the pattern of those used in magic lanterns, local crests, words, and faces were thrown upon those objects. Thousands of persons enjoyed this novel spectacle.

Propagation of Electromagnetic Waves.—Before a meeting of the Bradford Scientific Association a few days ago, Dr. Riley (president) introduced the subject of the "Propagation of Electromagnetic Waves." He referred to the recent researches of Dr. Hertz, of Vienna, who proved experimentally that the waves are transmitted with a velocity of about 185,000 miles a second. In conclusion, it was pointed out that light-waves were undoubtedly electromagnetic waves, and that the electromagnetic theory of light propounded by the late Prof. Clerk Maxwell had received splendid confirmation from the brilliant achievements of Dr. Hertz.

Tunnel-Driving by Electric Motors.—It is expected that the improvements made in drilling and quarrying machinery during the last few years, especially by the introduction of electric power, will enable the proposed Simplon tunnel to be constructed at a cost and rate which will place its predecessors in the shade. Motive power is now easily obtained from water in the Swiss mountainous districts, and the facility with which electric power can be transmitted renders the site of the generating station a matter of small moment. Five and a half years is the stipulated period for completing this tunnel, which it has been decided to carry out.

Breakdown of a Supply Station.—One of the most extraordinary causes of stoppage in the supply from a generating station is that which is reported from a country town in the United States. The boiler feed supply is obtained from a small river apparently well populated with small crabs. A number of these got into the feed pipes and effectually choked them, so that shortness of water led to a shut down and stoppage of traffic. The two morals to be drawn are: first, the importance of a grid at the feed inlet; second, the popularity of electric traction even in country places.

The "O. E." Electricity Meter.—This meter, which is adapted to all the requirements of electric supply, forms the basis of an excellent wall catalogue or list just issued by Mr. Joseph Edmondson, of Hey-street, Longside lane, Bradford. The catalogue, in addition to giving particulars of the "O. E." electricity meter, contains details concerning the conductivity, resistance, and fusing point of different metals and alloys and the effect of temperature on resistance per cent. per degree Fahrenheit; also the diameter, current capacity, resistance at 60deg. F. per 1,000 yards, and weight per 1,000 yards of single wire, and of 7, 19, 37, 61, and 91 strand cables.

The British Association. The council of the British Association have made the following nominations as presidents of sections at the Oxford meeting in August next: Mathematical and Phyiscal Science, Prof. A. W. Rücker, of the Science and Art Department; Chemistry, Prof Harold Dixon, of Owens College; Geology, Mr. L. Fletcher, Keeper of the Department of Minerals, British Museum; Biology, Dr. T. B. Balfour, Professor of Botany at Edinburgh University; Geography, Captain W. L. Wharton, Hydrographer to the Admiralty; and Anthropology, Sir William Flower, Director of the Natural History Department of the British Museum.

To Local Authorities.—From the Board of Trade returns and elsewhere it is known that many local authorities have obtained or intend obtaining provisional orders, while few have actually entered upon the practical work. A movement is on foot—organised by Mr. H. Scholey, of 22, Paternoster-row—to provide lecturers, who shall be at once capable and unbiassed, to put before local authorities and their constituents the true position of electric lighting and power transmission from a commercial point of view. Lectures will be given, illustrated with diagrams and experiments, in any town upon the payment of a reasonable fee and expenses. We understand that several capable lecturers have agreed to the scheme, which ought to be useful.

The Pacific Cable.—The *Canadian Gazette* states that in the Queensland Assembly on October 11, during consideration of the estimates of the Postmaster General's department, Mr. Dickens asked whether the Government were prepared to make an arrangement with Sir John Pender for a reduction of the cable rates between Queensland and London. Sir Thomas McIlwraith, the Premier replied that the Government declined to be a party to the monopoly of the Eastern Extension Telegraph Company. The policy of the Government was to have a free hand and to subsidise a second cable. This led to a discussion of the question of subsidy to the New Caledonian cable, and, in reply to a question, Sir Thomas McIlwraith stated that the agreement between Queensland and the French company provided for the payment of £2,000 per annum for 30 years.

France and Telegraphy.—A commission has been formed by the French Posts and Telegraphs Department to investigate the question of the international telegraphic

communications of France. The work of the commission consists in drawing up a programme of all the telegraphic communications, the establishment of which is deemed necessary in the interest of France, the estimation of the cost of the various lines, and the order in which the works should be carried out. After an exchange of views at the first assembly of the members of the commission, in the course of which it was declared that it is now more imperiously necessary than ever to organise a system of French submarine telegraphic cables, the commission instructed a sub-commission to elaborate a comprehensive plan, and to prepare certain projects, the carrying out of which was regarded as particularly urgent.

The Electric Light Saved Money.—In giving the toast of "Prosperity to the Association" at the twenty-eighth annual dinner of the Leeds Association of Engineers on Saturday, Mr. Reginald Wigram, who occupied the chair, observed that an important development of the year had been the progress made in the use of electricity. Experimentally, it was shown at the Frankfort Exhibition that they could produce electricity at the Falls of the Rhine and light Frankfort with it. That certainly pointed to a diminution in the use of coal. Why should not Leeds have water power brought to it by electricity from a point up in North Yorkshire 50 or 60 miles off? He stated that in certain works at Bolton as much electric light might be had for 4s. 4d. per annum as of gas for 5s. 6d. a year, and that in the Exchange Restaurant in Manchester the use of electricity saved £800 a year.

Wrought-Iron and Steel Tubes.—Judging from the new catalogue just issued by Messrs. James Menzies and Co., of 6, Lime street-square, E.C., and of the Phœnix Tube Works, Dalmarnock Bridge, Glasgow, the company seem to cover the whole of the ground comprised in the category of the manufacture of wrought-iron and steel tubes for practically all purposes. For instance, on turning the first pages of the pamphlet, one finds references to standard wrought-iron tubes for gas, water, and steam purposes, together with diameters, prices, and weight per foot in pounds for each particular object, and supplemented with details of short pieces, connections, bends, and other fittings. Then we come to lap-welded iron and steel tubes for locomotive, marine, and stationary boilers; next boring tubes for artesian purposes, Menzies patent flange joint and tubes for hydraulic purposes, and, finally, rain-water pipes and fittings.

Dust Destructors for Lighting.—In a lecture delivered the other evening before the members of the Yorkshire College, at Leeds, on the utilisation of town refuse, Mr. C. Rawson, F.C.S., observed that the results of a test made at Ravensthorpe showed the steam-producing power of refuse to be one-third that of good average coal. The amount of steam power thrown away was therefore considerable, and the best way to utilise the refuse was by treating it in a destructor, and applying the fuel portion to the generation of steam for driving dynamos. The refuse of Leeds, he remarked, would yield steam equivalent to 1,764 h.p. continuously day and night. The quantity of refuse to be disposed of in that city was estimated at 130,000 tons per annum, and assuming it to be of the same quality as that tested at Ravensthorpe, it would yield as much steam as 17,000 tons of good average coal. In like manner the refuse of Bradford should produce 948 h.p. continuously.

The Northern Society of Electrical Engineers. A new institution bearing this title has just been formed, with headquarters in Manchester, for the purpose of holding meetings for the promotion of electrical science and its commercial and other applications, and for social intercourse between members. The society has not been founded with any view of rivalry or opposition to the existing Institution of Electrical Engineers, but simply to enable members of the profession who are unable to attend meetings in London to do so in the provinces, and at the same time to become better acquainted with each other. We are informed that a large number of gentlemen has already joined the society, and that invitations have been posted to members of the profession within range of Manchester inviting their co-operation. At present it has been decided to hold the meetings in Manchester, but it is expected that at an early date gatherings will be arranged for at other provincial towns. Mr. John Darney, of 102, Portland-street, Manchester, is the hon. secretary.

Royal Institution.—The following are the lecture arrangements before Easter: Prof. Dewar, six lectures (adapted to a juvenile auditory) on "Air: Gaseous and Liquid"; Prof. Charles Stewart, nine lectures on "Locomotion and Fixation in Plants and Animals"; the Rev. Canon Ainger, three lectures on "The Life and Genius of Swift"; Mr. W. Martin Conway, three lectures on "The Past and Future of Mountain Exploration"; Prof. Max Müller, three lectures on the "Vedânta Philosophy"; Prof. W. H. Cummings, three lectures on "English Schools of Musical Composition" (with musical illustrations); the Right Hon. Lord Rayleigh, six lectures on "Light," with special reference to the optical discoveries of Newton. The Friday evening meetings will begin on January 19th, when a discourse will be given by Prof. Dewar on "Scientific Uses of Liquid Nitrogen and Air"; succeeding discourses will probably be given by Mr. A. P. Graves, Mr. T. J. Cobden-Sanderson, Prof. W. F. R. Weldon, Prof. Silvanus P. Thompson, Prof. John G. McKendrick, Dr. W. H. White, the Right Hon. Lord Rayleigh, and other gentlemen.

The Oscillation of Electric Sparks.—Prof. C. V. Boys, F.R.S., lectured on Monday evening at the London Institution on the subject of "When and Why an Electric Spark Oscillates." The lecturer, by a series of mechanical illustrations corresponding with their electrical equivalents, showed how when an electrical current passed round any circuit whatever through a piece of wire the space around that wire was magnetised. When an electrical current had magnetised the space around itself, and one tried to stop the current, the magnetism which had been induced could not suddenly cease to exist; but in dying out it urged the current on in the direction in which it was going, and was able to introduce a surprising effect. The magnetic force developed by an electrical current was able, if one tried suddenly to stop it, to give to the current the effect of momentum. There was no momentum in electricity by itself, but only in virtue of the fact that it magnetised the space round it. Electrical resistance and mechanical resistance were analogous to one another. Just as in the case of sound-waves, which travelled at a definite rate, so, in the case of electromagnetic oscillations, they took place in the medium connecting two discharge circuits with the waves. The electromagnetic waves which were thus set up did not travel slowly, but at the rate of about 187,000 miles a second.

Lighthouse Communication.—In the House of Commons last week Sir J. Long asked the Postmaster-General whether he would state what number of lighthouses on the coasts of the United Kingdom now had electrical communication, and to what further number it was proposed to extend such communication. In reply, Mr. A. Morley said that the number of lighthouses on the coasts of the United Kingdom which had been provided with electrical communication was 22. This number included Lundy

Island, Fair Isle, and the Gunfleet pile lighthouse. The Royal Commission on Electrical Communication with Lighthouses, etc., had recommended that communication be also extended to Caldy Island, the Tuskar, and the Fastnet. They had not yet reported as to any further extension. Sir J. Leng then asked the President of the Board of Trade what floating lightships now communicated with the Telegraph Department by electric cables, and whether it was intended to lay down electric cables to other lightships. Mr. Mundella observed that the work of connecting with the shore by electric cable the North Goodwin and the Kentish Knock light-vessels was being proceeded with as rapidly as practicable. He hoped they would be completed during the present financial year, and this, with the Gunfleet lighthouse, would exhaust the amount placed at his disposal for this purpose.

An Opportunity for Ladies.—"The great fall in the price of lamps," remarks a lady writer in the *Pall Mall Gazette*, "has led to the increased popularity of electric lighting, but the difficult problem to solve is where to place the light. So many people object to ceiling lights, and yet the greater part of Lord Salisbury's house at Hatfield is illuminated in this way. The chief objection to ceiling lights is that they are not pretty, and are difficult to shade, but there can be no doubt that this is the only way to light up large rooms. Branches from the wall only partially illuminate, and when properly shaded leave the rest of the room in darkness. Lamps are excellent for reading or table purposes, but they altogether fail to light the walls, or the upper part of the room and so prevent pictures from being seen at all, unless, of course, they have special lamps fixed in front of them. There is a great chance for anyone who wants to earn a living by making a speciality of advising on this point, since so many rooms are entirely spoilt by the inartistic manner of arranging the lamps. Another question which is exciting much attention in the feminine mind is the shading of the electric light. In nine cases out of ten the whole effect is spoilt by defective shading. In the next electric exhibition it is to be hoped that some new ideas on this very important point will be forthcoming. At present the matter is in its infancy. Here, too, is another opening for women who want something to do. The field is boundless, and no capital is required."

Royal Society Medals.—Lord Kelvin presented medals to the following at the anniversary meeting of the Royal Society last week: The Copley Medal to Sir George Gabriel Stokes, F.R.S., for his researches and discoveries in physical science; a Royal Medal to Prof. A. Schuster, F.R.S., for his spectroscopic enquiries and his researches on disruptive discharge through gases and on terrestrial magnetism; a Royal Medal to Prof. H. Marshall Ward, F.R.S., for his researches into the life-history of fungi and schizomycetes; and the Davy Medal to Prof. J. H. van't Hoff and Dr. J. A. Le Bel, in recognition of their introduction of the theory of asymmetric carbon, and its use in explaining the constitution of optically active carbon compounds. At the same meeting the following officers and council were elected for the ensuing year: President, Lord Kelvin; treasurer, Sir John Evans; secretaries, Prof. Michael Foster, Lord Rayleigh; foreign secretary, Sir Joseph Lister; other member of the council, Prof. Isaac Bayley Balfour; Andrew Ainslie Common, LL.D., Andrew Russell Forsyth, Sc.D.; Richard Tetley Glazebrook; Prof. Alexander Henry Green; Sir John Kirk; Prof. Oliver Joseph Lodge, D.Sc.; Sir John Lubbock, D.C.L.; William Davidson Niven; William Henry Perkin, LL.D.; the Marquis of Salisbury; Prof. J. S. Burdon Sanderson; Adam Sedgwick; Prof. Thomas Edward Thorpe; Prof. William Augustus Tilden; and Prof. W. Cawthorne Unwin. The dinner of the society took place on the evening of the 30th ult.

An Imperial Train.—The Imperial Austrian train is described at some length in a recent issue of the *Organ fur die Fortschritte des Eisenbahnwesens*, and elevations and sectional plans of the different cars are given. The train is made up of eight cars in all, beginning with a baggage car, which also contains a special compartment for the conductor and the electric plant for lighting the train. This is followed by a servants' car, after which come in succession the car of the emperor, a car for the emperor's suite, a dining-car, a special kitchen car, another car for additional members of the suite, and finally a combination servants' and baggage car. The current for lighting the cars is furnished both by a dynamo and a storage battery, the arrangement being such that the latter comes into action if through any cause the operation of the dynamo should become interrupted. The storage battery is capable of supplying the 67 lamps with which the train is equipped for a period of 10 hours. The train is heated by steam furnished from a special heating boiler, and the cars are all supplied with ordinary hand, as well as vacuum and Westinghouse, brakes. It would appear from this that the Emperor of Austria is not, after all, very much better supplied with railway luxuries than is the ordinary commercial traveller upon our corridor trains running to Scotland, except on the one point of exclusiveness and choice selection as regards travelling companions.

Gas-Engines as Prime Movers.—The electricity supply station of Waukesha is not a very extensive one, but it possesses some features of considerable interest as regards the type of prime movers adopted. These latter are two in number, an Otto gas-engine and an ordinary steam-engine, each of 100 h.p. The gas-engine has two horizontal cylinders with very heavy flywheel and driving pulley on the crankshaft. A countershaft is also provided, and this too carries a pulley of great weight. The speed of the engine averages 160 revolutions a minute, that of the countershaft is 690 revolutions. Leather belting is used to connect the shafts, and either engine is arranged with friction-clutches, so that it may drive any of three dynamos—one 80-arc lighter, one 75-arc lighter, and a machine for incandescent lights to the number of some 600. One or two machines may be driven from either engine, or both may drive all three. As a rule, the gas-engine is set to drive one of the arc lighters and the incandescent light machine; then at the time when the public lighting comes on, the steam-engine is started and the load transferred—the gas-engine taking the street lamp load. The total output is too heavy for either engine, generally speaking; but whenever light enough for one only, the gas motor is always used for choice. Careful experiments with this plant at different times show, amongst other things, what is not altogether surprising—viz., that an increase in the load under normal conditions tends to considerably reduce the cost of working per horse-power hour—so far as the gas consumption is concerned.

The Royal Society Anniversary.—The anniversary meeting took place on the 30th ult., at Burlington House The president (Lord Kelvin), in the course of his address, said that not the least important of the scientific events of the year was the publication, in the original German and in an English translation by Prof. D. E. Jones, of a collection of Hertz's papers describing the researches by which he was led up to the experimental demonstration of magnetic waves. For this work the Rumford Medal of the Royal Society was delivered to Prof. Hertz three years ago by his predecessor, Sir George Stokes.

Faraday, with his curved lines of electric force, and his dielectric efficiency of air and of liquid and solid insulators, resuscitated the idea of a medium through which, and not only through which but by which, forces of attraction or repulsion, seemingly acting at a distance, are transmitted. The long struggle of the first half of the eighteenth century was not merely on the question of a medium to serve for gravific mechanism, but on the correctness of the Newtonian law of gravitation as a matter of fact however explained. The corresponding controversy in the nineteenth century was very short, and it soon became obvious that Faraday's idea of the transmission of electric force by a medium, not only did not violate Coulomb's law of relation between force and distance, but that, if real, it must give a thorough explanation of that law. Nevertheless, after Faraday's discovery of the different specific inductive capacities of different insulators, 20 years passed before it was generally accepted in Continental Europe. But before his death, in 1867, he had succeeded in inspiring the rising generation of the scientific world with something approaching to faith that electric force is transmitted by a medium called ether, of which, as had been believed by the whole scientific world for 40 years, light and radiant heat are transverse vibrations. Faraday himself did not rest with this theory for electricity alone. During the 56 years which have passed since Faraday first offended physical mathematicians with his curved lines of force, many workers and many thinkers had helped to build up the nineteenth century school of *plenum*; one ether for light, heat, electricity, magnetism; and the German and English volumes containing Hertz's electrical paper, given to the world in the last decade of the century, would be a permanent monument of the splendid consummation now realised. The Royal Society's *Transactions* and *Proceedings* of the last 40 years contained in the communications of Gassiot, Andrews and Tait, Cromwell Varley, De la Rue and Muller, Spottiswoode, Moulton, Plucker, Crookes and Grove, Robinson, Schuster, J. J. Thomson, and Fleming, almost a complete history of the new province of electrical science which has grown up largely in virtue of the great modern improvements in practical methods for exhausting air from glass vessels, by which we now have "vacuum tubes" and bulbs containing less than $\frac{1}{1000000}$th of the air which would be left in them by all that could be done in the way of exhausting (supposed to be down to 1mm. of mercury) by the best air-pump of 50 years ago. A large part of the fresh discoveries in this province had been made by the authors of these communications, and their references to the discoveries of other workers very nearly completed the history of all that has been done in the way of investigating the transmission of electricity through highly-rarefied air and gases since the time of Faraday.

Gas-Engines and Accumulators for Central Stations.—A pamphlet has been issued by the Hagen Accumulator Works dealing with "Municipal Electricity Works with Gas Motors and Accumulator Working." The *brochure* is discussed by Mr. F. Uppenborn in the *Elektrotechnische Zeitschrift* of the 1st inst. The author gives a curve—the mean curve of the gasworks in Dresden, Magdeburg, Bremen, Carlsruhe, and Hagen in Westphalia—showing the consumption during 24 hours of the day of heaviest demand in the year. The curve, which is made to correspond with the consumption in watts in the conductor, shows that the demand is very variable, and that the greatest consumption takes place at about 5.30 p.m. As is well known, gas motors work most favourably, from an economical point of view, at full load when the amount of gas used per horse-power hour is the lowest, whilst the consumption per working unit considerably increases at low loads. If now the electrical distributing mains are supplied direct from the generators without the use of accumulators, the capacity of the machines must be so arranged as to meet the requirements when the demand is greatest. Thus gas motors would only in the most rare cases work with a favourable load. It is therefore an important advantage to arrange the operating conditions, so that during the whole of the working period, the gas motors are fully loaded, and the surplus energy used for charging accumulators. In this manner the energy contained in the accumulators serves during the hours of highest demand to assist the generators in supplying the network of mains. The size of the electricity works, or, rather, the horse-power, must be calculated to deal with the day of heaviest load. Reasoning in this manner by means of the diagrammatic curve already mentioned, a line is drawn showing the constantly even output of the machines during the 24 hours for feeding the network and charging the accumulators, whilst the consumption of current indicated above this line is that supplied by the batteries. By the employment of generators only, the horse-power must be such as to meet the greatest demand, but by the use of accumulators it is shown that five eighths of the engine power is saved, whilst at the same time the generators continuously work under the most economically favourable conditions. Let us consider the case where the supply of gas is furnished at 2s. 6d per thousand, this corresponding to the charges made by municipal gasworks to different large consumers. Let us assume two generating stations, each being equipped with three gas-engines of 120 h.p. each. Two of these motors, giving together 240 h.p., will feed a continuous-current three-wire system, whilst the third motor serves as reserve. Each station is able to supply 7,570 16-c.p. (50-watt) lamps simultaneously alight, or both stations 15,140 lamps. If of the number of lamps installed 66⅔ per cent. are calculated as being energised at the same time, this gives 22,710 incandescent lamps connected to the mains, or their equivalent in arc lamps. The radius of the area of supply is 830 yards, or if the two stations are 1,010 yards distant from one another, the combined supply district amounts to 2,780 yards. A pressure of 110 volts at the lamps is provided for with a loss in each outer conductor of 10 volts. There will therefore be required in each of the two stations three gas-engines, each of 120 h.p. (one as reserve), three shunt dynamos (one as reserve) of 110 volts and 697 amperes, capable of working at 120 volts and giving 662 amperes, and yielding at 145 volts 548 amperes; and one battery of 4,628 ampere-hours capacity, the charging current being 662 amperes, and the discharging current 1,060 amperes. The author then enters into the general method of working stations according to this method, and then comes to consider the commercial aspect of the question for two stations, each of 240 h.p. (with 120 h.p. each as reserve), and each capable of energising 7,570 16 c.p. lamps simultaneously. The cost of site, buildings, gas-engines, dynamos, accumulators, mains, etc., works out at £74,000; the annual receipts at ½d. per 16 c.p. lamp per hour, with 15,140 simultaneously burning lamps having an annual number of hours of burning of 750 each, comes to £21,574, and the annual expenditure, after providing for depreciation, totals £9,138. This shows a profit of £12,436, or a return of over 16 per cent. on the initial expenditure. Mr. Uppenborn, in conclusion, states that this system is eminently suitable for towns where the gasworks are the property of the municipal or other local authority.

KILLINGWORTH HEDGES.

Mr. Killingworth Hedges, M. I. C. E., M.I.E.E., was born at Streatham, Surrey, and educated at Brighton until the age of 16, when he was articled to Mr. James Easton, C.E., for five years, during which period he served his time in the shops of the firm of Easton and Amos. Subsequently, after passing the examination of the Royal Engineers Military Board at Devonport, he received a commission in the Royal Monmouthshire Engineer Militia, which he held for three years. His first connection with electricity was in 1878, when he was sent to Paris to report on the then recently-invented Jablochkoff candle. In 1879 he was employed to report to the Mersey Dockyard as to the suitability of the electric light for the Liverpool Docks, and afterwards carried out the present installation. He exhibited switches and arc lamps at the Paris Electrical Exhibition, and obtained a bronze medal; also at the Crystal Palace, where a silver medal was awarded him. He invented the fusible cut-out of metallic foil, which was perfected and used throughout the Vienna Electrical Exhibition, and for which a special certificate from the Scientific Commission was granted. He published a pamphlet entitled "Useful Information on Practical Electrical Lighting," in 1879; and a book with the same title in 1881. He is the author of "The Supply of Electricity by Local Authorities," also "Precautions on Introducing the Electric Light;" of a paper entitled the "Fire Risks of Electric Lighting," read before the Royal Institute of British Architects in 1884; and was awarded a Telford Premium by the Institution of Civil Engineers for his paper on "Central-Station Lighting," published in vol. lxxxviii. of the *Minutes*, 1887, a book entitled "Continental Electric Light Stations" being published not long after. More recently he gave his attention to the question of doing away with oil in bearings, and has invented a special form of carbon material, termed "carboid," which permits of the bearing being heated to a considerable temperature without materially increasing the friction, and has been successfully adopted.

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.

BY J. T. NIBLETT AND J. T. EWEN, B.Sc.

XV.

RESISTANCE, *continued.*

Verniers.—As verniers, such as the one just alluded to, are now applied to many instruments where great accuracy of reading is desired, a short account of the methods of constructing and using these extremely useful aids to exact reading is introduced here.

The vernier, so called after its introducer, is a device for assisting the accurate reading of equally-divided scales. Suppose that it is desired to read off a given linear or circular scale to, say, tenths of the smallest division. The pointer or arm which slides along the edge of the scale is made broad enough to have engraved upon it a little subsidiary scale, known as the vernier, whose total length is equal to either nine or eleven of the scale divisions on the large scale, and which is itself divided into ten equal parts. In practice, it is found much more convenient for reading purposes to make the length of the vernier equal to nine scale divisions rather than eleven, whence it is sometimes termed a *nonius*. In all of the three examples of verniers illustrated in Figs. 37 to 39, the length of the vernier has been made equal to nine scale divisions.

The zero-point of the vernier is itself actually the pointer for reading the scale, the other ten lines which constitute the vernier scale being merely for accurately determining the position of this zero-point. Thus, suppose that the vernier zero, which is usually distinguished by an arrow-head or by being made diamond-shaped as in Figs. 37 to 39, is exactly opposite any one of the lines on the main scale, say 822, as shown in Fig. 37. Then the reading of the pointer is exactly 822, or 822·0. But as a vernier division is just equal to one-tenth of nine scale divisions—that is, nine-tenths of a scale division—the next line on the vernier is just one tenth of a scale division behind the next line on the scale.

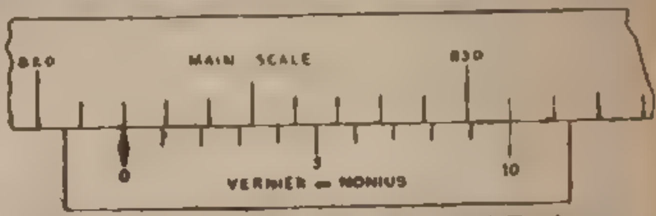

FIG. 37.—Equally Divided Linear Scale, with Vernier.

Similarly, the second line from the zero on the vernier is two tenths behind the next line on the scale, the third line three-tenths, and so on, the ninth line being nine-tenths behind, and the tenth ten-tenths, so that this last just coincides with the ninth scale line past the one opposite the vernier zero, as will be observed in Fig 37.

From this it will be evident that if the first line of the vernier past the zero coincides with a scale line, the reading will be just one-tenth of a scale division more than if the vernier zero had been the coincident line. When the second vernier line coincides, the reading is two-tenths more, when the third, three-tenths, and so on; therefore, to state it generally, when the *n*th line of the vernier coincides with a scale line, the pointer or zero line of the vernier is just *n*-tenths of a scale division beyond the scale mark which it has last passed.

In this way is obtained a very simple and extremely accurate method of reading a scale. First note which of the scale lines the vernier zero has just passed, then observe which of the vernier lines has a scale line most nearly opposite it. The reading of the vernier in this way, counting from the zero, will give the value of the scale reading to tenths of a scale division, with great precision, even although the scale divisions are small. In certain instruments where the scale divisions are very small, microscopes are attached to the scales to facilitate the reading of the verniers.

FIG. 38. - Equally Divided Circular Scale, with Radial Vernier.

FIG. 39. -Equally Divided Cylindrical Scale, with Vernier.

The application of the vernier to various kinds of equally-divided scales is illustrated in Figs. 37 to 39. Fig. 37 shows the application to an ordinary linear scale, the reading of which in the position of the vernier shown is 822·0, as has been already explained.

Fig. 38 shows a portion of an equally divided circular scale, with a vernier reading to tenths of a scale division engraved on the end of a radial arm pivoted at the centre. The reading of this in the position shown is 31·98, as the last scale line passed by the vernier zero is 31·9, and the eighth vernier line is the one which is just opposite to a scale line. Angular surveying instruments, such as theodo-

lites and the like, are usually furnished with scales of this kind, but subdivided rather differently. In an ordinary transit instrument reading to minutes, the main scale or circle is generally divided into half-degrees, and the vernier consists of an arc whose length is equal to 29 of these, divided into 30 equal parts. In theodolites of greater precision, the main circles are made larger and divided into third parts of a degree, and the verniers have a length equal to 59 of these, divided into 60 equal parts, so that they read to thirds of a minute or 20 seconds. In some of the larger astronomical telescopes, where extreme accuracy is of paramount importance, and a very slight error in reading an angle may utterly vitiate an astronomer's calculations, the main circles are made very large and the verniers read to single seconds. In electrical measurements, however, angles are never read to a precision at all approaching this, measurements which depend upon magnitudes of angles for their readings being as a rule only approximate.

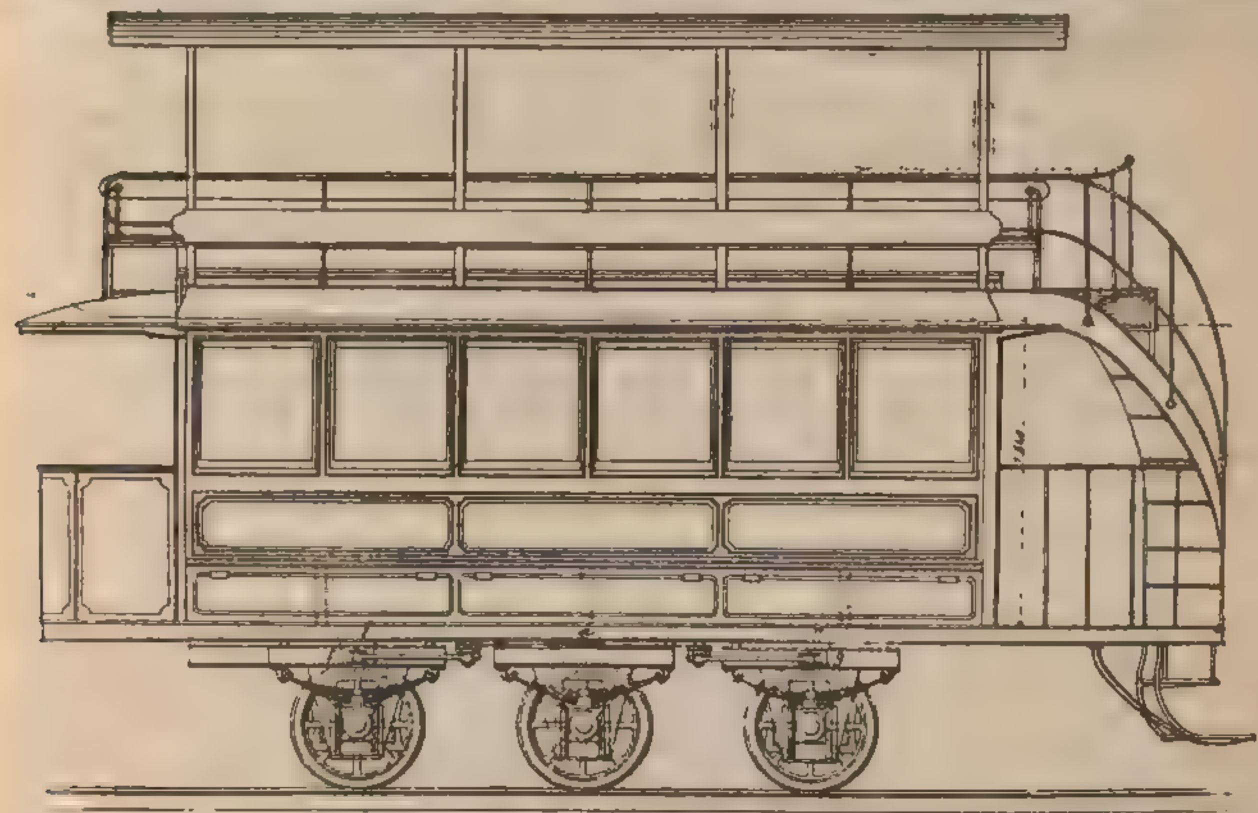

FIG. 1.—General View (in Side Elevation).

In Fig. 39 is shown a portion of a cylindrical surface with an equally-divided scale engraved upon it, and provided with a vernier on a similar cylindrical surface, reading to tenths of a scale division. Most planimeters are read by means of a scale and vernier of this description, the vernier being fixed rigidly to the instrument while the scale is on a roller running on the paper; and as has been already mentioned, Sir William Siemens used this arrangement in some of the later forms of his differential resistance measuring instrument, instead of the flat linear scale and vernier with which the instrument illustrated in Fig. 36 is provided. In the example shown in Fig. 39 it will be seen that the vernier zero lies somewhere between 15·8 and 15·9 on the main scale, and that the fifth vernier line coincides with a scale line. The reading of the scale in the position shown is, therefore, 15·85.

When the total length of a vernier reading to tenths of a scale division is made equal to eleven instead of nine scale divisions, then each vernier division is just equal to eleven-tenths of a scale division—that is, one-tenth more instead of one-tenth less, as in all the examples shown. In this case the vernier has to be read in the opposite direction to the main scale, and errors in reading are apt to arise. Thus suppose the main scale reads from left to right, then the zero mark of the vernier, instead of being at the left, is at the right side of the vernier scale, which has to be read in the opposite direction to the main scale—that is, from right to left.

(To be continued.)

BATTERY CARS IN PARIS.

The electrical engineer learns by experience his constant need of a *nil admirari* state of mind, and hence he considers more or less carefully all the new electrical schemes and projects brought forward, in case there may be a grain or two of wheat amongst a heap of chaff.

Practically it would appear axiomatic that inasmuch as accumulator working has not as yet proved at all successful on tramways where the conditions of employment are fairly favourable, such a method is hardly worth putting into further practice until the ruling conditions of lines or of accumulators are changed.

However, there are circumstances under which even the heavy load of accumulators and motor gear may not prove too great a disadvantage for operating ordinary tramcars; and the Compagnie Générale des Omnibus, of Paris, has for some time been experimenting in this direction to see what practical results can be achieved with a fair amount of success. This company has throughout employed accumulators of the Laurent-Cély type as manufactured by the Société pour le Travail Electrique des Metaux.

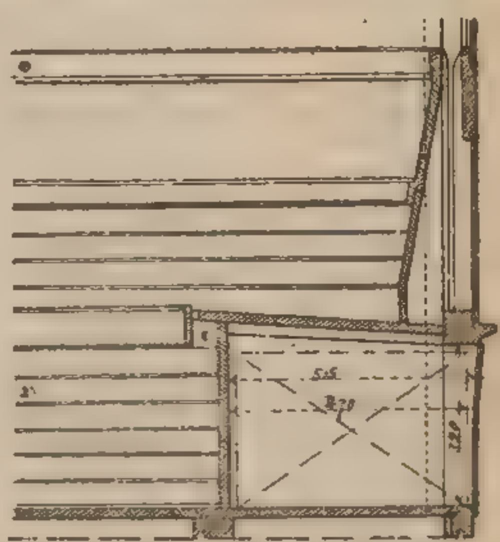

FIG. 2.—Cross-Section through Car-Seat, showing Accumulator Space.

In their first experiments a system of double-reduction gear was employed to connect the motor and car axles, but being desirous of having as little complication of parts as possible, whilst also lessening the noise and wear, the company accepted an offer from the firm of Bréguet to build motors of slow speed suitable for mounting direct upon the tramcar axles. The weight of each gearless motor thus constructed was about three tons, or nearly double that of the high-speed machines previously used. Their input was 10 kilowatts, or 100 amperes at 100 volts. The field-magnet system was suspended from the framework of the vehicle by means of powerful springs, whilst *the armature was mounted upon* a brass sleeve with bearings on the tramcar axle. A flexible connection between the two was provided by means of a disc or ring with four notches, into which were slid four arms projecting from the axle.

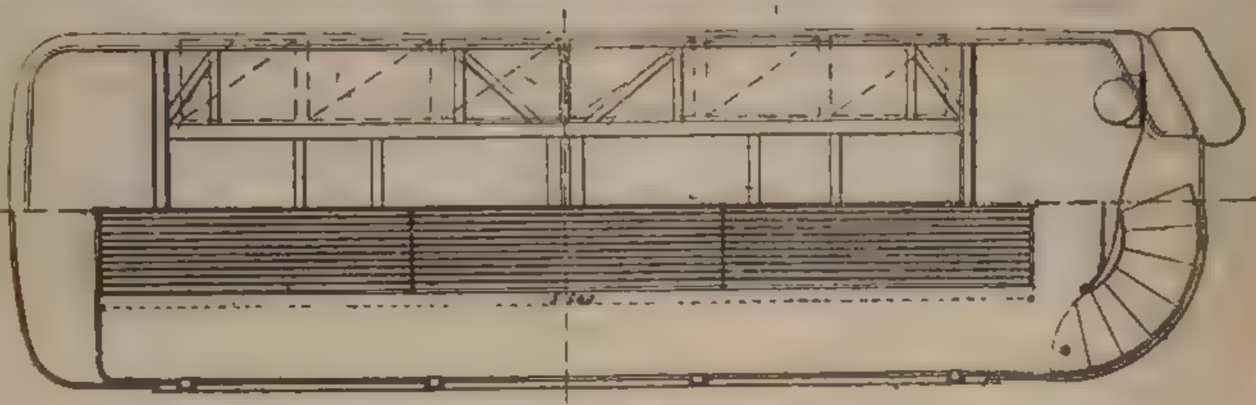

FIG. 2.—Half Plans of Car Floor and Frame.

These gearless motors proved in practice to be even less of a success than the double-reduction arrangement, and the *sors tertia* of a single-reduction gear was then decided upon. This, the latest and, it is expected, the most suitable type, is illustrated in the annexed engravings, reproduced from the *Revue Industrielle*. The arrangement of accumulators is very much the same as in the previous experiments, the Laurent-Cély batteries being placed in three compartments under each seat lengthways of the

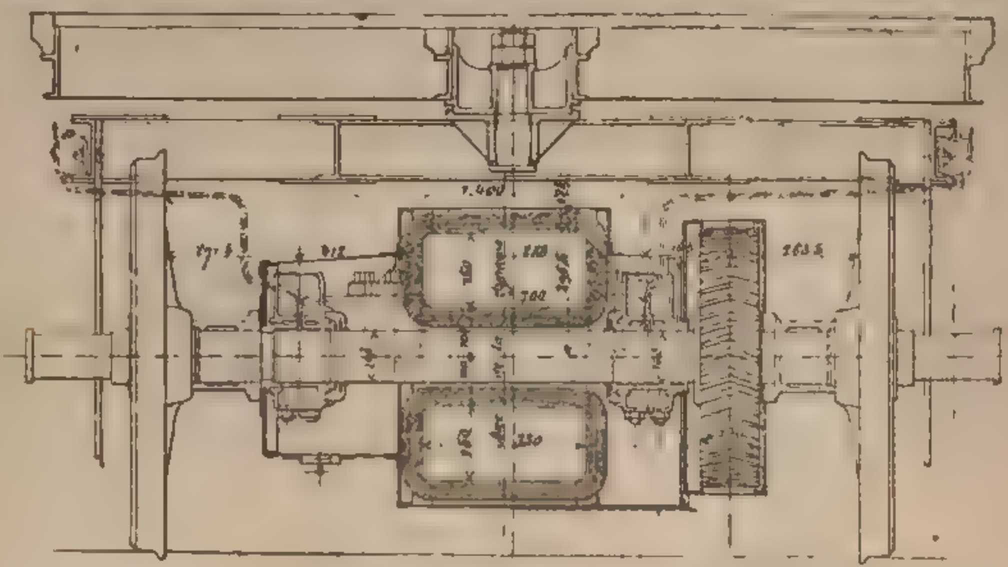

FIG. 4.—Vertical Section Along Line C D (Fig. 5).

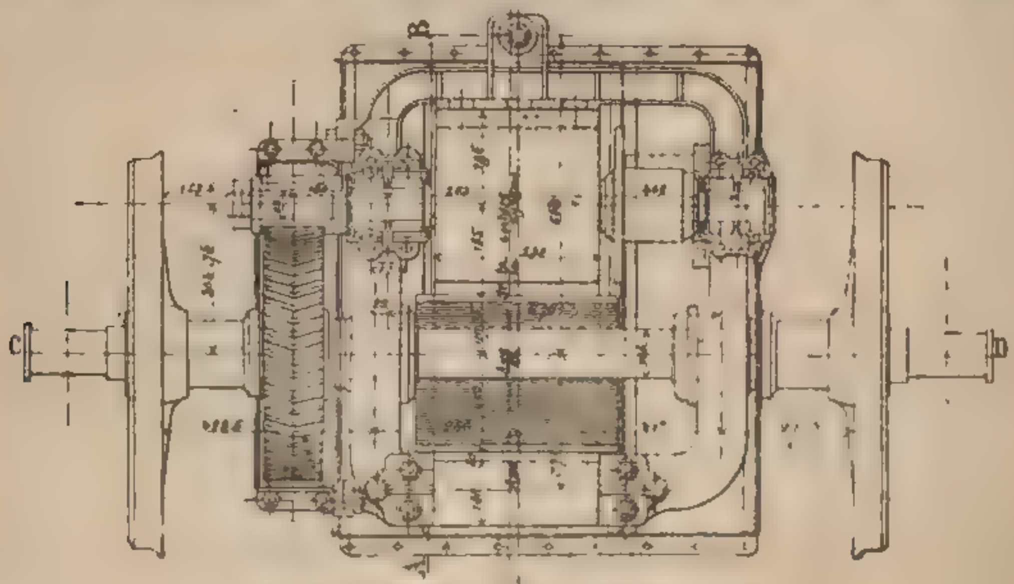

FIG. 5.—Plan and Horizontal Section Along Line E F G H (Fig. 3).

vehicle. Each of these compartments contains two sets of nine cells joined in series, and built up of 11 plates each, five positive and six negative, weighing in all about 400lb. per set. There are, consequently, 108 cells in all, and a total weight—including boxes and other accessories—of some $3\frac{1}{2}$ tons of accumulators. The accumulator spaces and compartments are shown in Figs. 1, 2, 3, giving side elevation, plan, and end elevation respectively.

The reduction gear employed gives a speed ratio between the motor and tramcar axles of, roughly speaking, 5 to 1; a double helical arrangement of tooth is adopted, and every

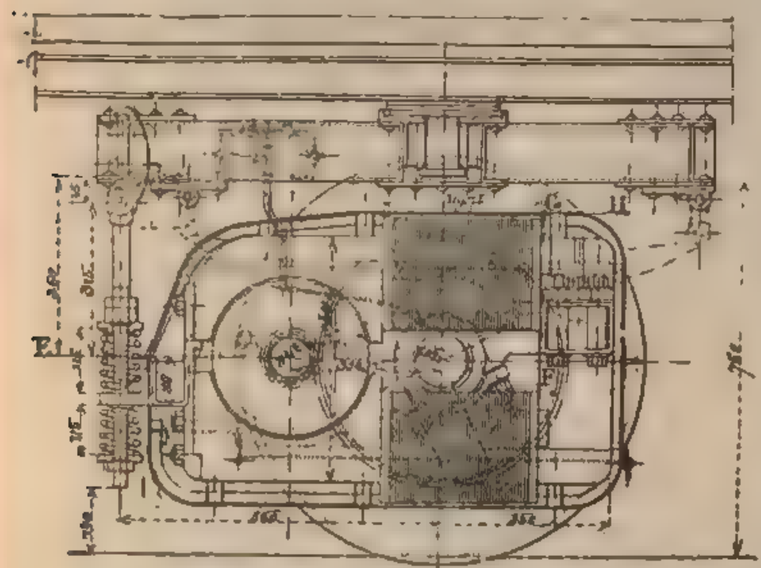

Fig. 6.—Vertical Section Along Line A B (Fig. 5

care taken to ensure accurate and easy running. Apart from any economy in working, there is a considerable saving

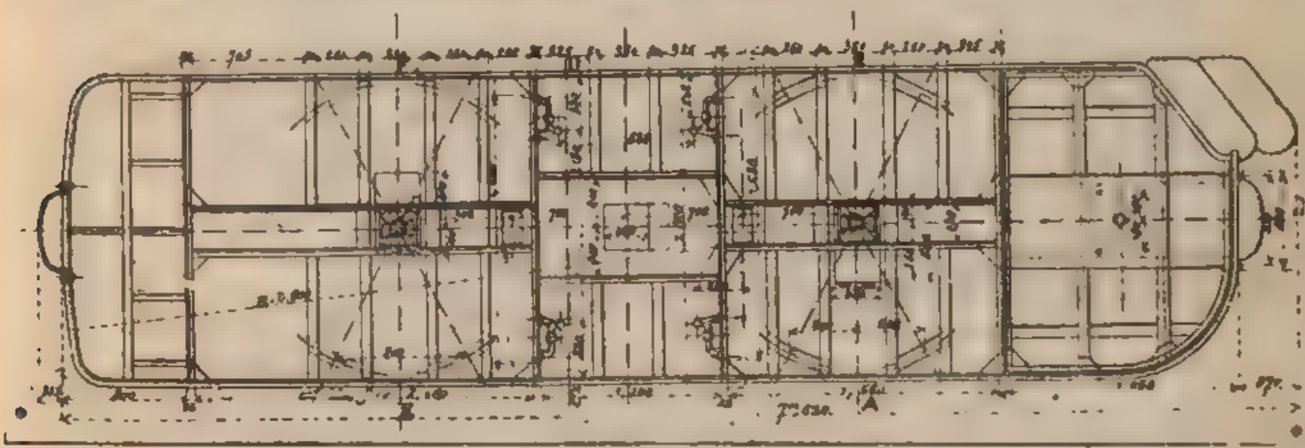

Fig. 10.—Plan of Car-Frame.

effected in weight, the total weight of motor and gear being only about $1\frac{1}{2}$ tons, as compared with double that amount

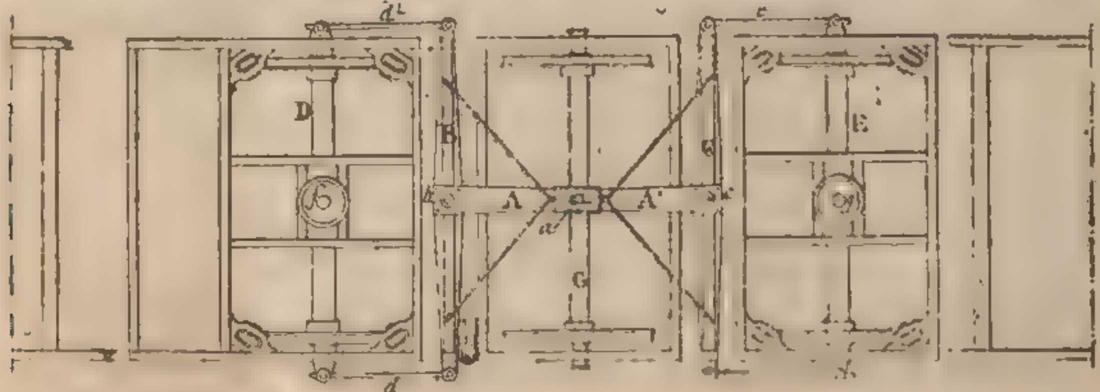

Fig. 11.—Plan of Truck Frames, showing the Radial End Trucks and Guide-Rods.

for the gearless motors. The use of steel for the pole-pieces has so far given working results much better than were expected, and of course implies a saving in weight. In

Figs. 4, 5, 6, and 7 are shown views of the motors and gear: two shunt-wound motors are fitted on each car.

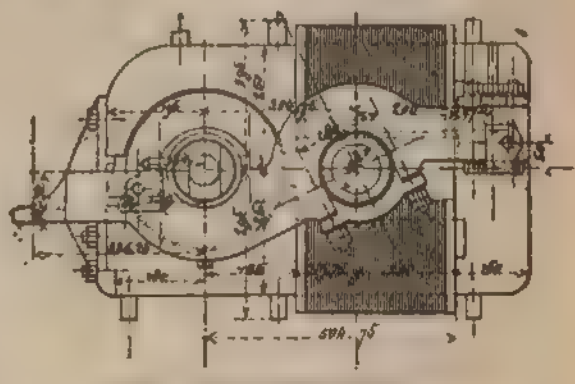

Fig. 7.—Side Elevation of Motor.

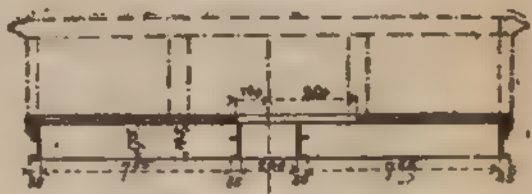

Fig. 8.—Vertical Cross-Section Along Line E F (Fig. 10).

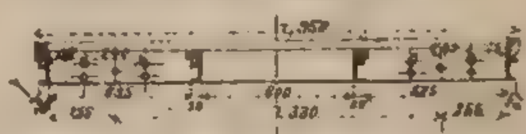

Fig. 9.—Vertical Cross-Section along Line, C D (Fig. 10).

The energy supplied to the motors in accordance with the requirements of the work to be done is in this instance regulated by varying the motor fields after the usual fashion; not, however, by cutting in or out different sections of the field windings, but by introducing a variable outside resistance into the shunt and thereby varying the current which passes through it.

The regulator handle, which serves to effect these variations, and thereby stops or checks the vehicle more or less rapidly, also acts as a reversing lever; it operates two contact rings, one of which gives the various movements in forward or backward gear, putting on the brakes and closing or opening the magnet circuit, whilst the other regulates, according to requirements of power from time to time, the strength of the magnetic field.

Precautions are taken to avoid sparking, when the main circuit is made or broken, by a series of intermediate contacts with resistances, so that the main current is only cut off from one contact to another when the respective by-pass is open; and the same thing is done with the shunt current. A rush of current through the field, before magnetisation, is prevented by employing for closing the shunt circuit an additional contact operated by the main regulator handle.

Perhaps the most interesting feature of this new type of car is the flexible system of trucks or motor axles adopted.

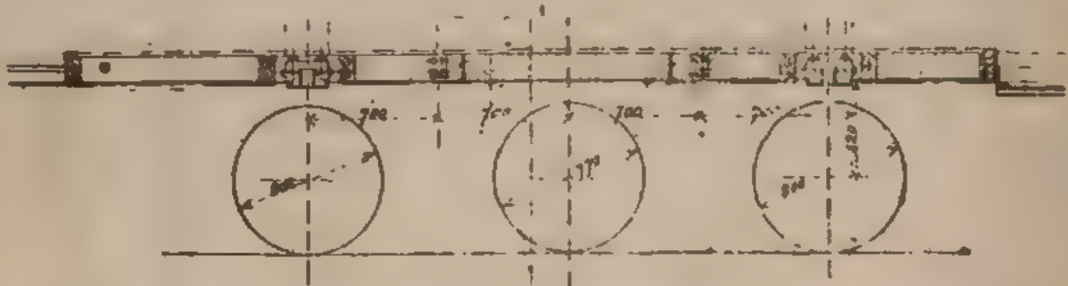

FIG. 12.—Vertical Section (length-ways) of Car-Frame.

The axles on each car are three in number; those at each end serve to carry the motor, and with the truck frames which they support, have a radial motion as well as a slight play backwards and forwards in the framing, so as to allow of easy running round curves. A system of arms, swivelling on the centre axle, give the requisite swinging movement round a massive pin, *a*. Gudgeon pins at *b* and *c* are attached to the car frame, and slide in small slots in the swivelling truck frame, thereby serving to limit the motion of the latter. This system of flexible yet strong connection between the car axles is due to M. Garnier, and the details of it are clearly seen in Figs. 8, 9, and 10. Figs. 11 and 12 illustrate cross-sections of the car framing. Curves of a radius as low as 40ft. are successfully operated by means of these trucks.

HEAT GENERATED IN ELECTROLYTIC CELLS.*

BY G. E. ALLAN, B.SC.

This paper is a record of experiments begun in March, 1892, by Mr. F. W. Dunn, B.A., and myself, to find what heat was given off in certain electrolytic cells—viz., those in which the electrodes were of zinc and platinum. Our first intention was to have cells of Pt. Pt., Zn. Zn., and Pt. Zn. in battery acid of the proportion of 1 to 8, the electrolysis to be performed by the current from the Pt.-Zn. cell, but the current given by two cells of this kind was so small that the rise of temperature was inappreciable. I may say that we afterwards found a current of one-tenth ampere did not always give heat to balance the cooling of the air. To remedy this we took sulphuric acid of the best conductivity — Matthiessen giving that sulphuric acid diluted with water to a specific gravity of 1·215 at temperature 12·3 C., or almost exactly 30 per cent. acid, has the least specific resistance of any combination of sulphuric acid and water. But even this did not give a workable result, so we had recourse to outside help, and after this used a current from a battery of accumulators. Our preliminary experiments showed us that the cells stand in the following order as regards rise in temperature: Zn. Pt. with the lowest rise, then Zn. Zn., Pt. Pt., and Pt. Zn.; the first-mentioned metal in each case being the anode.

Some of the particulars which we took during each *experiment* were: the quantity of liquid in each cell

(generally about 500 c. cm.); the temperature of the air, at intervals of time, by cells of water placed between the others; the difference of potential between the electrodes of each cell; and the weight of zinc consumed at electrodes of that metal, besides recording the temperature of each cell and the strength of the current at fixed intervals.

The specific heat of the acid was found to be ·82; and as regards the consumption of zinc, Woodward gives the following figures on the heat which is due to the chemical action of the acid on the zinc:

Heat from 1 gm. Zn on changing to ZnO, 1,314 g.w.u.
Heat from this ZnO on dissolving in H_2SO_4, 360 g.w.u.
Heat absorbed by dissociating O from water, 1,061 g.w.u.

Total per gm. zinc, 613 g.w.u. (g.w.u. stands for gram-water-unit). So that in calculation of the heat due to chemical consumption of zinc we had only to multiply the weight of zinc used by 613. Joule gives that 100 grains ZnO on dissolving in H_2SO_4 are able to raise 1lb. of water 6·88deg. F.

One great cause of trouble to us at first was the shaking of the platinum plates when the liquid was stirred. Corrugation of the plates was tried. This was no use. At last the Pt. plates were stiffened by welding them on to rectangular frames of glass tube bent into the shape of the plates. In this state they were firmer than the zinc plates. The platinums gave us a little trouble after this by sometimes coming loose from their frames. Dr. Bottomley suggested that this might be due to the occulsion of hydrogen. It is very probable that this was the case—Graham having shown that platinum occludes hydrogen to some extent when it is made the negative electrode of a voltaic couple, and expands with the absorption.

CONTINUATION OF EXPERIMENTS WITH FIRM PLATINUM PLATES.

*Paper read before the Physical Society of Glasgow University.

In these experiments the current was not regulated to a particular value, but its strength was read off at intervals from the ampere balance which we used for that purpose, and during the experiment the current gradually decreased, electrolytic resistance increasing with rise of temperature. From the number of observations made during the experiment there was no time left to work a rheostat, even if we had wished to keep the current constant. But this was done in the later experiments. In November the work was continued, in order to find which plate in each cell became the hotter.

Three cells were used—those of Z P., Z Z., and Pt.Z. The two plates in each vessel were separated by a blotting-paper partition, and there was a thermometer at each plate. There were no stirrers used, the temperature being taken by placing the thermometer at the centre of the plate before reading it.

RESULTS.

Current.	Rise in temperature.						Time of current.
	Z.	P.	Z.	Z.	P.	Z.	H. M.
1·0	1·73	1·83	1·68	1·58	2·88	2·58	1 0
1·0	1·02	1·17	1·07	1·22	2·42	2·27	1 0
0·5	0·41	0·43	—	—	0·76	0·66	0 30
0·5	0·94	1·09	·74	·94	1·40	1·40	1 0
0·5	0·47	0·62	·72	·67	1·17	1·07	1 0
0·25	0·06	0·11	·31	[illegible]	0·71	0·61	1 0
0·25	0·05	[illegible]	·0	·15	0·3	0·1	1 0
0·1	[illegible]	0·26	·06	·11	0·66	[illegible]	1 0

From the last set of experiments it will be seen that in the Z.-P. and P.-Z. cells the platinum was always hotter than the zinc, with one exception (February 10)—when they were equal in the P.-Z. cell. In the Z. Z. cell, twice the anode was the warmer and the cathode five times. Several experiments were made with a current of ·1 ampere, but the season of the year (February) was not suitable for observing the heating effect of such small currents, there being sometimes a fall of temperature during the experiment instead of a rise.

After this a different method was tried, but as it involved the use of tube in which a great rise of temperature took place, the results obtained from it cannot be so reliable. Taking two zinc plates, each in a beaker by itself, the two vessels were connected by a syphon tube 18in. long and ½in. bore with 3in. legs. The capacity of the tube was 70 c. cs., and there were 500 c. cs. of acid in each cell. The following results were obtained with this method:

Current.	Cell.	Rise in temperature.		Time.
		Anode.	Kathode.	H. M.
1·0	Z Z.	1·07	2·07	0 30
1·0	Z.P.	·83	1·53	0 30
1·0	P.P.	1·32	2·02	0 30
1·0	P.Z.	1·58	1·68	0 30
1·0	P.Z.	1·0	1·2	0 25

Here the cathode is always the hotter, no matter what cell, although in the last two the rise is much nearer equality than in any of the others. At the end of half an hour the connecting tube became so hot that it could hardly be held in the fingers. It must have been about 70deg. C. Again this method was changed for another. The syphon tube was inverted, placed on a stand, and the electrodes were put into the legs. Zinc sheet and platinum foil were shaped into small cylinders to fit the legs of the U-tube and the thermometers were put inside the cylinders.

Current ampere.	Cell.	Rise in temperature after two minutes.		Rise in temperature after 10 minutes.	
		Anode.	Cathode.	Anode.	Cathode.
·5	Z. Z.	2·45	3·1	16·7	11·9
·5	Z. Z.	2·3	2·45	14·8	11·75
·5	Z. P.	2·65	3·3	20·2	15·9
·5	P. Z.	4·45	3·7	19·45	13·35
·48	Z. P.	2·1	2·2	15·9	10·2

When observing, the temperature had to be read every minute, the increase in temperature being very rapid. These experiments showed that the final temperature of the anode was always greater than that of the cathode, although when zinc was the cathode it showed a rapid rise at the beginning, and this might explain why in former experiments the results were not uniform for the Z.-Z. cell.

These investigations are still in an unfinished state, and I am sorry they are not in a more advanced condition before being placed before the society.

AN EXTENSIBLE ELECTROLIER.

We illustrate an electrolier by an American designer, Mr. A. Rivenburgh. It consists of a tube containing strips of conductive metal connected with the wires of the house circuit, a tube of insulated material sliding therein, and having contact springs which connect to conductors leading to the lamps through the sliding tube. Fig. 1 shows the electrolier complete, Fig. 2 being a transverse section, and Fig. 3 the top portion of the sliding tube. The hole in the

FIGS. 1, 2, AND 3.

main tube is preferably rectangular, and the metallic strips in its opposite sides are flat. The springs connecting the strips, on the upper end of the sliding tube, are insulated from each other and connected with the wires extending down the inner tube and leading to the lamps. Additional strips of insulation are inserted in the walls of the main tube to prevent the springing of the metallic strips, and, to hold the sliding tube in any desired position, a spring and a set screw, which may be made to bear upon it, are arranged in the side of the main tube.

STREET-LIGHT TESTING.

Athens is a thriving city in the State of Georgia (United States) and deserves notice, if only because the arc lights which illuminate its streets are provided and maintained by the Athens Gaslight Company. Some at least of the gas interests are wide awake to their most prudent course. The city authorities of Athens, however, grew suspicious of the illuminating intensity of the arc lamps, and authorised a series of tests to determine whether or not the company was complying with their contract as to candle-power. The tests conducted so far by the city engineer have been made with a Bunsen photometer. A sperm candle consuming 120 grains per hour was used as the standard. The tests were conducted as follows: The light to be tested was lowered to within about 5ft. of the street surface, the photometer placed with the opening in one end in the direction of the electric light, and the candle used as a standard was placed 1ft. from the greased diaphragm and opposite the opening in the other end. With the photometer in this position the instrument was moved back and forth until the image appeared the same in each mirror. The square of the distance of the lamp from the centre of the instrument was taken as the candle-power of the light tested.

JOHN TYNDALL.

The world is poorer in intellect to-day than it was when last we wrote. A leader has passed away; aye, a greater leader than most are willing to admit. Few among the sons of men are left in whom truth and justice, honour and loyalty, are above monetary considerations. True to himself, true to his friends, true to his country, a hater of shams, a despiser of sycophants, a detester of opportunism, lived and died John Tyndall. Adversity had no terrors, prosperity brought no false pride, energetic in the pursuit of scientific truth, bold and blunt in expressing his convictions, he feared none, but walked through life earnestly endeavouring so to conduct his affairs as to leave the world better than he found it. He suffered because of his honesty, for he had the courage of his opinions—and in a worldly sense this trait in a man's character does not usually increase his prosperity. The world would not be worth living in were it not leavened by such as he. Our admiration for the late professor has hardly any bounds, for to us he was a many-sided hero. What was his endowment? Not wealth, not private tutors and college lectures, not time to study; nothing more than great natural ability, a keen desire to know, and a determination to excel. With these the unknown lad took a position among the great ones of the earth. A stupendous task fully achieved. Perhaps our greatest admiration, however, is for the teacher. Three classes of men take almost equal rank in this world, and first of these is the teacher, next to whom we would place the scientific truth-seeker, and then the honest politician. The teaching ranks, again, would take two classes—those practising religious teaching and those occupied with more mundane affairs, though to separate the one from the other in the real teacher is somewhat difficult. Who was it that described a genius as one capable of taking infinite pains? The real teacher is a genius. Tyndall was a real teacher, and he had an almost superhuman power of taking pains. Examine his treatises, "Heat a Mode of Motion," "Sound," "Forms of Water," and find, if you can, a redundant word or an undigested sentence. Commencing with the simplest and most understandable experimental facts, he gradually, by adding simple to simple, builds up a perfect explanation of the most complex phenomena. The matter, method, and manner of his lectures at the Royal Institution or elsewhere, were not one jot inferior to his written books. Clear and concise, every word of use, illustrated by diagrams and experiments, fitting so accurately and explaining so beautifully, that the meanest intellect amongst the audience could not fail to grasp the argument and agree with the conclusion. We have by his death lost a great teacher, but his influence will live. Some of our young readers may not understand the value of Tyndall's work. They will not recognise him as a great electrician, perhaps not as a great physicist as reputations now go, but to some of us who lived and worked a few decades ago his influence is known to be that of an era maker. Darwin has long gone to his rest, Tyndall now

follows, leaving amongst us Huxley to represent a triumvirate whose names will linger in scientific history as long as history itself endures. Have they not taught the world to be slow in coming to conclusions, to investigate carefully, systematically, and thoroughly; that rash assumptions are often worthless and unprofitable; and, above all, that the aim of the scientific man is to establish the truth? A few brief words as to Tyndall's life and this attempt to express the regret we feel at the loss the world has sustained must be concluded. Tyndall was descended from a worthy English stock, one of his ancestors being W. Tyndale, a translator of the Bible, the family belonging to Gloucestershire. The late Prof. Tyndall was born in 1820 in Ireland, in the village of Leighlin Bridge, near Carlow, his father being but an humble tradesman. The youth was kept at school till his nineteenth year, when he entered the Ordnance Survey service, afterwards going to a Manchester firm. In 1847 he became a master at Queenswood College, Hants, and next year went with Frankland to Marburg to study chemistry. In 1850 he made Faraday's acquaintance, and from that time his life's work, till 1887, was connected with the laboratory of the Royal Institution. In the latter year he retired to live at Hind-head, where he wanted quiet to finish certain work which he had set his mind to accomplish. Unfortunately, time has not been given him to complete that work. Of his scientific investigation his books must speak. Of himself the poet speaks:

> Thou art gone,
> And he who would assail thee in thy grave,
> Oh, let him pause! For who among us all,
> Tried as thou wer't . . .
> Ah, who among us all
> Could say he had not erred as much or more?

TOWING BY ELECTRICITY.

The adaptation of electrical energy in any new direction deserves attention, and when we consider the decadence of canal traffic upon our English canals anything which promises to assist in resuscitating their activity will be welcomed. In America and in France experimental trials have been made in regard to electric towing. France claims precedence in this new departure, both as regards point of time and extent of experiment. Here upon the Bourgogne Canal, nearly four miles long, with more than half the length in tunnel, for the past two months electric, has successfully replaced horse towage. There are two stations wherein Gramme machines are driven by water power, one at each end of the canal. The Gramme machines are put in series, and parallel line wires arranged so that the motor placed between takes off from one wire, making the return through the other. The motor drives by two sets of gearing—one for light and the other for heavy load. With a light load, the distance was run in about 45 minutes, using a current of about 12 amperes; with a heavy load of 17 boats carrying 1,500 tons it took two hours, using a current of 20 amperes. The normal speed of the motor is 1,000 revolutions per minute. Accumulators are used as regulators. The American experiment is of a different character, and has been carried out on the Erie Canal. The Legislature voted a sum of 10,000dol. for investigating the merits of electricity as a motive power on canals. An ordinary steam canal boat was taken, the engine and boiler replaced by two 25-h.p. Westinghouse street-railway motors of standard type, connected direct to the propeller shaft. The line wires were erected much as on street railways, and two trolleys used to connect with line and return. These overhead wires were of No. 0 copper trolley wire strung 5ft. apart. A current at 500 volts pressure was promised, but in the end a pressure only of from 200 to 250 volts was obtained. The results in this case were very successful. We do not mean to indicate that the problem of electric traction upon canals has been completely solved, nor have we any information as to cost. That electrical towage is possible is certain, whether it can be made commercially successful is another question. In many cases, as at the Bourgogne Canal, the prime motor power may cost nothing, but even then the cost of an installation and maintenance will be considerable. English canals are comparatively little used. Some people contend that this is the result of railway competition and ownership; others assure us that it is the result of the product time and cost. At any rate, those interested in the matter ought to consider how far electricity will help them to a renewal of activity.

CORRESPONDENCE.

THE LATE ANTHONY RECKENZAUN.

SIR,—Will you allow me a space in the columns of your journal, which has amongst its readers so many of my late husband's friends, to thank them for sending me, in such numbers, letters of sympathy and condolence?

Their number is far too great for me to reply to them individually, and I hope you will give me this opportunity of expressing to them my warmest thanks, and the gratification it is to me to know how universally my husband was beloved and respected.—Yours, etc.,

34, Hemberton-road, S.W. E. RECKENZAUN.

INSTITUTION OF ELECTRICAL ENGINEERS.

The following is the house balloting list for Council and officers for the year 1894:

PRESIDENT.

Alexander Siemens, M.Inst.C.E.

VICE-PRESIDENTS (*four to be elected*).

R. E. Crompton, M Inst.C.E.
Sir David Salomons, Bart., M.A.
Sir Henry Mance, C.I.E., M Inst.C.E.
Prof. George Forbes, F.R.SS. (L. and E.).

ORDINARY MEMBERS OF COUNCIL (*12 to be elected*).

Frank Bailey.
Prof. J. A. Fleming, M.A., D.Sc., F.R.S.
Walter T. Goolden, M.A.
Gisbert Kapp, M.Inst.C.E.
Prof. A. B. W. Kennedy, F.R.S., M.Inst.C.E.
W. M. Mordey.
Prof. John Perry, D.Sc., F.R.S.
James Swinburne.
*Major A. H. Bagnold, R.E.
*W. B. Esson.
*Robert Kaye Gray.
*Augustus Stroh.

ASSOCIATE MEMBERS OF COUNCIL (*three to be elected*).

*G. K. B. Elphinstone.
*Dr. W. E. Sumpner.
*The Earl Russell.

* Recommended by Council.

POLYPHASE ALTERNATE CURRENTS.

(Continued from page 465.)

Alternate-Current Motors.

The third of the desiderata mentioned in the last article is that of means to transform the electric energy of alternate currents into mechanical energy, and is specially interesting because it offers solutions to the two others.

Since alternate currents were first used there have been constant demands for a practical alternate-current motor The problem has been solved in various ways, which may be passed in review. Alternate-current motors can be divided into three classes:

1. Motors with constant magnetic field.
2. Motors with alternating magnetic field.
3. Motors with rotating magnetic field.

1. Motors with Constant Magnetic Field.

If an alternate current traverse an armature of any kind placed in a constant magnetic field, and if this armature has been first brought to an angular velocity correspondent to the alternate current, the rotation will continue synchronously with that of the alternator which produces the current. But if the mechanical resistance increases too much the synchronism is destroyed and the motor stops.

To render the motor self-exciting, M. Zipernowski has devised the part commutation of the alternating current as a shunt, using the redressed current to produce the magnetic field. Under these conditions synchronism is more easily kept.

These motors have a high efficiency. For certain applications synchronism is not a defect, but an advantage. But the necessity of first bringing the motor to speed causes their rejection for most purposes.

2. Motors with Alternate Magnetic Field.

If an alternate current is passed into a continuous-current motor, the latter begins to turn. But the loss by hysteresis, and especially eddy currents, is enormous. This can be obviated by using laminated magnets for the armature. By suppressing iron altogether we arrive at the electro dynamic motor which is used by Elihu Thomson for his motors.

Mordey has proposed to rectify the current by a commutator placed upon the axle of the motor. At start, the effect is nil, but as the speed increases it becomes more nearly as in a continuous-current motor.

In motors with closed circuits, the armature coils, being subject to the action of an alternating field, are the seat of E.M.F.'s. By closing them upon themselves at a suitable moment, they produce a motor couple which makes the armature rotate. This class of motors has not been employed because of the low efficiency—and small specific power (in the case of the electro-dynamic motor).

3. Motors with Rotating Field.

Motors of this class are based upon Arago's experiment showing how Foucault currents generated in a disc of copper over which magnets rotate will eventually put this disc in motion, until the same or almost the same speed as that of the magnets is attained.

With regard to the production of a rotating field by means other than the rotation of a magnet, it was in 1888 that Ferraris showed that when two alternate currents of the same period, but displaced, traversed two circuits making a certain angle with each other, the resultant of the two fields so produced is a rotating field to the extent of one turn per period. Under certain conditions the field may turn with uniform movement and constant intensity.

If a circuit closed on itself is placed in a rotating field, it is the seat of induced currents which cause it to rotate in the same direction as the field and with the same speed. Further, diphase currents of various kinds can be obtained from a single current, thus:

(*a*) By employing the current itself and a current produced by a transformer whose primary is traversed by the main current (Ferraris).

(*b*) By combining two circuits whose time-constant is very different (Tesla).

(*c*) By employing a second circuit closed on itself and making a certain angle with the circuit traversed by the alternate current. A current is therein developed by induction which creates the second alternating magnetic field necessary to the production of a rotating field (Shallenberger).

(*d*) Lastly, Hutin and Leblanc propose a general method based upon the use of condensers.

Generally it is considered more convenient to produce polyphase currents direct by a special machine. Two currents can be used, conducted by four wires, or by three (with common return)—Ferraris, Tesla; but as it is necessary to have at least three wires, it is better to have three currents displaced one-third period, remembering that at each instant their algebraic sum is nil—that is, at each instant one conductor may serve as common return for two others (Bradley, Dobrowolski, Haselwander, Wenstroem). This is the class of motors we wish particularly to study.

The Rotating Field.

Rotating magnetic fields can be produced by any number of alternate currents suitably displaced. We distinguish diphase, triphase, or polyphase according to whether two, three, or more currents are used.

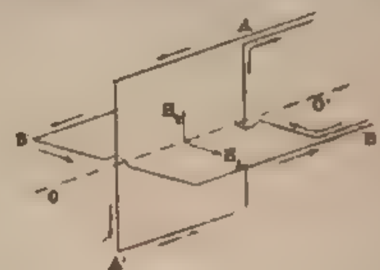

Fig. 8.

Consider two similar coils, A A' and B B' (Fig. 8), making a right angle between them as shown, and traversed by two currents having the direction shown by the arrows. Let these be alternate currents with the same periodicity, T, and same amplitude, A. The current in A A' at any given moment, t, is

$$C_1 = A \sin \frac{2\pi}{T_1} t;$$

or, putting $\omega_1 = \frac{2\pi}{T_1}$ $\qquad C_1 = A \sin \omega_1 t.$

If the current in B B' is a quarter of a period in advance at the given moment, t, its current will be

$$C_2 = A \sin \frac{2\pi}{T_1}\left(t + \frac{T_1}{4}\right) = A \cos \omega_1 t.$$

Supposing the law of current variation to be sinusoidal, which is practically true.

Fig. 9.

If H_o is the intensity of field produced by current, A, traversing one of the coils, then the intensities of fields produced by C_1 C_2 respectively, are

$$H_1 = H_o \sin \omega_1 t,$$
$$H_2 = H_o \cos \omega_1 t,$$

and as these are at right angles to each other the resultant field is

$$H = \sqrt{H_o{}^2 \sin^2 \omega_1 t + H_o{}^2 \cos^2 \omega_1 t},$$

that is to say, H_o.

1. *Diphase Field.*—Let α be the angle made by the resultant field at the moment, t, with the plane A A': we have:

$$\tan \alpha = \frac{H_1}{H_2} = \tan \omega_1 t.$$

It follows from this that the resultant field in the conditions given has a constant intensity and turns with an angular velocity, ω_1—that is, makes one turn per period of the alternate currents. Its direction is *f*, Fig. 9, if we suppose the current, B B_1, in advance of A A_1, and the initial rotation established as in the figure.

Practically, to obtain a more intense field the right-angle arrangement is replaced by a field-magnet system with laminated iron plates, insulated one from the other to avoid eddy currents. For example, the arrangement in Fig. 10 may be adopted. An iron ring carries four windings, AA', BB', united in pairs, as shown. It is easy to see that we shall have a rotating field identical to that just described.

To transmit these two alternate currents, only three conductors need be used. The strength at each instant in the

FIG. 10.

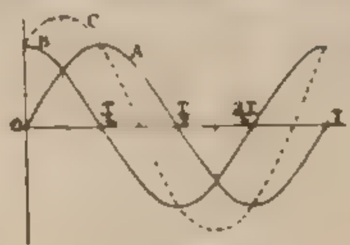

FIG. 11.

return wire undergoes variations, as shown in Curve C, Fig. 11.

Its value is at the moment, t

$$C_1 + C_2 = A\ (\sin \omega_1 t + \cos \omega_1 t).$$

If we simply assume that the specific loss of energy in this conductor never exceeds the maximum value that it attains in one of the other two conductors, the section of return wire will be given by the relation:

$$\frac{C_1{}^2 \max}{s^2} = \frac{(C_1 + C_2)^2 \max}{s'^2},$$

s being the section of one of the two conductors, and s' that of the common return.

The maximum of C_1 is A;

That of $C_1 + C_2$ is $A\sqrt{2}$;

Whence $\qquad s' = s\sqrt{2}.$

It is necessary to remark that often the section adopted for the conductors, s, would be capable of carrying a current of greater intensity than A without danger from heating. More often s will have been determined by the loss of energy allowed on the line. In this case we can adopt for the third wire this same section, s, without increasing the loss in the line, and thus realise a saving of a quarter of the copper.

As a fact, the loss per period with four conductors of section s and resistance r was:

$$W_4 = \frac{4\, r\, T_1 A^2}{2}.$$

In the case of three conductors of identical section the result was the same.

2. *Triphase Field.* —In this case three currents of the same

FIG. 12.

FIG. 12B.

amplitude and period are employed, but displaced one-third period, Figs. 12 and 12B. At a given instant, t, their strengths will be—

$$C_1 = A \sin \omega_1 t;$$

$$C_2 = A \sin \left(\omega_1 t + \frac{2\pi}{3}\right);$$

$$C_3 = A \sin \left(\omega_1 t + \frac{4\pi}{3}\right).$$

Putting $\omega_1 = \frac{2\pi}{T_1}$, the strengths of the three fields at the same instant will be—

$$H_1 = H_o \sin \omega_1 t;$$

$$H_2 = H_o \sin \left(\omega_1 t + \frac{2\pi}{3}\right);$$

$$H_3 = H_o \sin \left(\omega_1 t + \frac{4\pi}{3}\right);$$

calling H_o the strength of the field produced by the current of intensity A circulating in one of the coils.

FIG. 13.

To estimate the strength of resultant field, it may be noted that H_1, H_2, H_3 make angles of 120deg. $\left(\frac{2\pi}{3}\right)$ between themselves. Take two axes: oy following H_1; and xx' perpendicular to oy. Let x_1, x_2, x_3, and X; y_1, y_2, y_3, and Y be components of the magnetic intensity of the fields following these two directions, Fig. 13; we shall have

$$X = \frac{3}{2} H_o \cos \omega_1,$$

and

$$Y = \frac{3}{2} H_o \sin \omega_1 t.$$

The strength of the resultant field is at the moment, t, therefore equal to

$$H = \sqrt{X^2 + Y^2} = \frac{3}{2} H_o.$$

This strength is constant.

The value of its components X and Y show us, moreover, that the field turns with a speed $\omega_1 = \frac{2\pi}{T}$, that is to say, one turn per period of the currents.

It is well to remark here that the algebraic sum of the strengths of the three currents is constantly nil: thus

$$C_1 + C_2 + C_3 = A \left[\sin \omega_1 t + \sin\left(\omega_1 t + \frac{2\pi}{3}\right) + \sin\left(\omega_1 t + \frac{4\pi}{3}\right)\right]$$

$$C_1 + C_2 + C_3 = 0.$$

It follows from this that to transmit these three currents the return wires could be suppressed by joining the three ends of the circuits. At each instant one conductor acts as return to the other two.

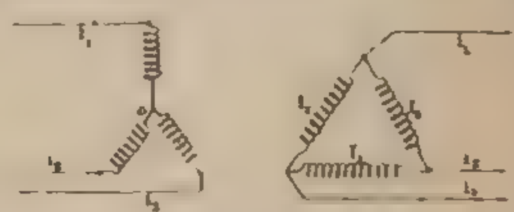

FIG. 14.

The three windings are practically arranged on a laminated inductor, in a similar manner to that indicated for the diphase field. They can be grouped in two ways—in star-shape or as a triangle, Fig. 14. The grouping in star form seems to be the best; indeed, a slight asymmetry in the three coils only causes an insignificant disturbance in the splitting up of the currents. It is not the same with grouping in a triangular form.

(To be continued.)

GOOD "CONTACT" ON ELECTRIC RAILWAYS.

Our American contemporary the *Street Railway Review* tells us once more of the difficulty experienced in getting good electric contact on electric tramways, and illustrates two examples of recent design in such contacts. The first, Fig. 1, is that of H. R. Keithley, and is known as the "Chicago bond," being used in that city. From one piece of copper a bond is rolled with thimble or tube-shaped ends. These ends being inserted in the holes, the edges of the tubes are bent back to temporarily hold the bond in place, and an iron plug is riven in the tube. This plug manifestly expands the soft copper tube so that it makes a moisture-proof contact, and at the same time one of large area.

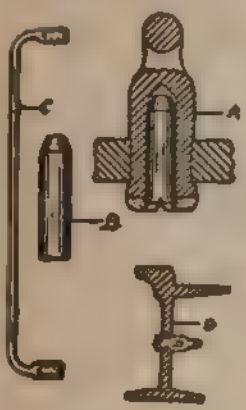

FIG. 1.

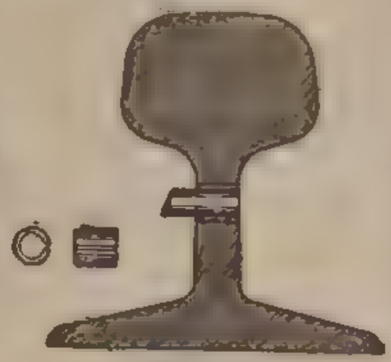

BUSHING BOND.

FIG. 2.

The principle of expanding a tube to fit a hole is the same as that used in putting in boiler flues, and if it is possible to expand an iron flue to a watertight fit it is evident that a soft copper tube can be so expanded.

A second system, Fig. 2, also from Chicago, shows another design to solve the difficulty by means of a spring bush. The bushing is a slightly tapered ring with a $\frac{1}{32}$in. split down one side. It is slipped over the end of the contact plug, and driven in a manner like to a channel pin. In driving the slit spring closes, and makes continuous contact over the entire circumference of the contact-piece.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE V.

(Concluded from page 522.)

The Paris System of Distribution of Power by Compressed Air.—The Paris power distribution is at present the largest in Europe, but it developed out of very small beginnings. About 1870 MM. Popp and Resch established, first in Vienna and then in Paris, a system for regulating clocks by impulses of compressed air. At first in Paris there was a central station in the Rue Argenteuil with two small compressors delivering air into a receiver at two to three atmospheres pressure. In a second receiver air was maintained at a constant pressure of 1¼ atmospheres. Two clocks (one in reserve) actuated a distribution valve, allowing air to pass into the mains for 20 seconds in each minute. By means of small pipes, laid chiefly in the sewers, the air impulses were conveyed to the clocks which were to be regulated. At the clock a small bellows lifted a rod at each impulse and moved the escapement of the clock. The air mains were generally ⅜in. to ¾in. in diameter, and the service pipes into the houses ¼in. to ⅜in. in diameter. These pipes were extended over many miles, and in 1889 there were in Paris 8,000 clocks regulated by the pneumatic arrangements.

The system proved so successful that a new central station was erected in Rue St. Fargeau, in Belleville. Down to 1887, two small Farcot engines and a beam engine sufficed for the work.

Gradually there arose a demand to use the compressed air for small motors. An extension of the station was then made, and a second installation erected in the Rue St. Fargeau. This consisted of six Davey Paxman compound engines, each driving two compressing cylinders. The engines developed 2,000 h.p. The compressors were made in Switzerland, on the Blanchard system. Soon this plant became insufficient. A third installation was erected in the Rue St. Fargeau, in 1889. This consisted of five compound engines and compressors, built by the Société Cockerill, at Seraing, the compressors being on the Dubois-François system. These engines developed 2,000 h.p. Finally, another central station, at the Quai de la Gare, was erected, with engines of 8,000 h.p., and room for extension to 24,000 h.p. The engines are triple vertical engines, with Riedler compound compressors. The air is compressed so much more cheaply at the new station that the old station in the Rue St. Fargeau is no longer worked.[*]

At the St. Fargeau station neither the engines nor the compressors were of the best type. Their effect was to compress 265 cubic feet of air at atmospheric pressure to six atmospheres per indicated horse power hour. The cooling in the compressor cylinders was ineffective. The air from the six compressors was delivered into eight cylindrical receivers of 1,150 cubic feet capacity each.

The air was then distributed by cast-iron mains, 11·8in. in diameter. These had joints with indiarubber rings forming a kind of stuffing box, and permitting expansion at every pipe length without leakage. The mains are laid partly under roadways, and partly in sewer subways. They are supplied at intervals with automatic draining boxes. It was remarkable that the demand for power from this station so rapidly grew up to its full capacity.

The air motors used were generally of a simple kind. For small powers a simple rotary engine was used. For larger powers steam-engines were employed, worked with air instead of steam. Where the compressed air enters a building it generally passes through a screen which removes solid impurities. Then there is a stop valve and a meter for measuring the air. Next, there is often a reducing valve by which the pressure is reduced to 4½ atmospheres. In most cases there is a reheater, often a simple double walled box of cast iron, in which the air circulates, and is heated by a coke fire. For a 10 h.p. motor this reheater is about 21in. in diameter and 33in. high. The amount of coke used is not considerable, about ½lb. per horse-power hour. The air is raised in temperature to 300deg. F. The air motors are very convenient. They can be started at any moment, they are free from inconvenience from leakage, heat, or smell, and they require a minimum of attendance.

Often the exhaust can be used to cool and ventilate the working-rooms. The air motors are used for various purposes. At some of the theatres and restaurants they drive dynamos for electric lighting. At some of the newspaper offices there are motors of 50 h.p. and 100 h.p., driving printing machines. In workshops there are motors driving lathes, saws, polishing, grinding, sewing, and other machines. At the Bourse de Commerce, the compressed air drives dynamos for electric lighting, and also is used to produce cold in large refrigerating stores. In many of the restaurants air is used for cooling purposes. It is also used to work cranes and lifts directly, a water cushion being used between the working cylinder and the lift.

In the first compressors at the Rue St. Fargeau, about 265 cubic feet of air was compressed to six atmospheres per indicated horse-power hour. The second installation had somewhat better compressors. These compressed about 300 cubic feet of air per indicated horse-power hour.

Later, permission was given to Prof. Riedler to convert one of the Cockerill compressors into a compound compressor. After the change, 370 cubic feet of air were compressed to six atmospheres per indicated horse power hour. In the large new compressors at the Quai de la Gare, 438 cubic feet of air are compressed per indicated horse power hour. The general result of the working of the new station is that a cubic metre of air is compressed to seven atmospheres for 0·4 centime, or about four-tenths of the cost of compression at the older station.

In the new station the steam engines are vertical triple engines, working compound compressors with two low and one high pressure compressing cylinders. Each engine is of 2,000 h.p. Four have been erected, three being regularly worked and one kept in reserve. The new station has been placed on the banks of the Seine, where coal and condensing water can be obtained cheaply. Steam of 180lb. per square inch pressure is used, and the makers guaranteed that the engines would work with 1·54lb. of coal per indicated horse-power hour. The new air-main, about seven kilometres in length, is 20in. in diameter.

Compressed Air System at Offenbach, near Frankfort on Maine.—A compressed air distribution of the most improved type has been constructed at Offenbach by the firm of Riedinger, of Augsburg. The compressing station has a horizontal compound steam engine, with crankshaft and flywheel. The air compressors are compound, of Riedler's design. The air is compressed to two atmospheres in the first cylinder, and then to six atmospheres in the second. The heat is abstracted in an inter cooler between the high and low pressure cylinders. The steam cylinders are 22in. and 31in. diameter and 40in. stroke. Each air cylinder is worked direct from the back of the corresponding steam cylinder. The engine is stated to work with 15½lb. of steam per indicated horse-power hour, and the efficiency of the compressor is 87 per cent. The

* Howard Lectures delivered before the Society of Arts.

[*] For numerous details and data relating to the Paris system, see "Neue Erfahrung ueber die Kraft versorgung von Paris durch druckluft." Von A. Riedler, Berlin, 1891. "La Distribution de la force par l'air comprimé dans Paris," par Prof Riedler. Paris, 1891.

engine runs at 75 revolutions, or 490ft. of piston speed per minute. The air is distributed through 23,000ft. of cast-iron mains, with indiarubber ring joints. The main, when tested with a pressure of 6½ atmospheres kept up for 70 hours, showed a leakage of only 1·6 cubic feet per mile per hour.

Distribution of Power by Steam.

Most commonly where steam power is used, the boilers which generate the steam are near the engines which generate the power. But in special cases it has been necessary to convey the steam some distance before it is used in engines. Sometimes pumping machinery underground has been worked from steam boilers above ground by steam conveyed in pipes, protected as far as possible from heat losses by radiation. It would, nevertheless, hardly have been thought very reasonable to distribute steam widely for power purposes through pipes but for a secondary object. Steam distributed from a central station can be very conveniently used for heating purposes as well as for power purposes. The defects of steam as a means of distributing power may be balanced by its convenience as a means of distributing heat. At any rate, in America the experiment of distributing heat and power from a central station by steam has been tried on a very large scale, and with a considerable amount of success.

In 1877, Birdsill Holly took out a patent for a system of steam distribution for heating purposes only. The steam was carried in pipes, having anchored stuffing boxes at distances of 100ft., so that the expansion and contraction of the mains was provided for. The pipes were protected against radiation by asbestos and wood. Steam was distributed to each building through a reducing valve, and used at low pressure in heating coils in the ordinary way. The condensed steam was discharged through steam-traps into the sewers. Generally the condensed steam, before being discharged, was taken through coils in a chamber where the air entering the building was warmed, and the condensed steam reduced in temperature to about 100deg. Plants on this system were erected in many towns. In Lockport, for instance, in 1879, the main steam-pipes extended a distance of 16,000ft.

As early as 1869 Mr. Emery investigated the problem of distributing steam in New York,* and the result of his studies was the creation of the largest system of steam distribution hitherto erected. Mr. Emery concluded that steam could be economically distributed from one station to buildings within a radius of half a mile.

In New York 10 plots for stations were secured, and work commenced in 1881. So far as the author knows, there are now two steam stations in New York, a down-town station termed Station B in Greenwich-street, which has boilers working to about 16,000 h.p., and an up-town station in Fifty-eighth street, designed for boilers of 3,000 h.p., and having about half this power at work.

The pipes from the down-town station extend through about 5½ miles of streets; those from the up-town station through 2¼ miles of streets. They work with steam at 80lb. to 90lb. pressure per square inch. The main pipes are of wrought iron, 16in., 15in., 13in., and 11in. in diameter outside, and about ½in. less in diameter inside. Return mains were also laid for the condensed water. These were 6in. and 8in. in diameter near the stations, decreasing to 4in., and even to 2½in., towards the ends of the pipe lines. More recently the return mains have been disused on account of their rapid corrosion.

The steam is used for a great variety of purposes, in addition to the principal purpose of warming buildings. It is used for driving engines for various manufacturing purposes, for driving engines for electric lighting, for engines working lifts, and for engines for ventilation. In 1887 there were some 500 engines worked with steam from Station B.

Prevention of Loss by Heat Radiation.—To prevent loss by radiation, the pipe is surrounded by non-conducting material. For this purpose, in different cases very different materials have been used. Straw laid parallel to the pipes, and covered with loam, is effective; but there have been used felt, cork, fossil meal, *papier mâché*, slag wool, and asbestos. Slag wool, obtained by blowing superheated steam through molten slag, is exceedingly efficacious, from the large amount of air it retains in the interstices of the wool; but if it gets moist, the sulphur it contains causes rapid corrosion of the iron pipes. Probably, with any of the coverings mentioned, moisture would also be very injurious.† It is, therefore, important to keep the outside of covered pipes dry, and this is best secured when the pipes are kept continuously heated.

In the case of the New York steam supply, the pipes are laid in brick trenches, the brickwork being kept 4in. away from the pipes. The pipes were coated with hot asphalte varnish, and the space packed with slag wool. Over the pipes a roof of short planks smeared with tar and bedded in cement is used, and a covering of tarred paper over the planks was carried well down the side walls to exclude percolating moisture.

The general arrangement of the pipes is to have an expansion joint every 50ft., and two intermediate joints, all the joints being carried on brick piers with a stone cap. At all dips in the pipe traps are connected for discharging the condensed steam.

Quantity of Power Transmitted by Steam-mains.—It is assumed that the velocity in the mains is u, and v is the specific volume of the steam, then the weight in pounds of steam transmitted per second, in a pipe of section Ω square feet, is

$$W = \frac{u}{v}\Omega;$$

if we take $u = 80$ft. per second,

$$W = c\,\Omega,$$

where c is a constant for any pressure.

Gauge pressure.	Absolute pressure.	v Cubic feet per lb.	c
lbs. per sq. in.	lbs. per sq. in.		
45	60	7·04	11·36
75	90	4·81	16·63
125	140	[illegible]	25·15

Suppose that, in accordance with Mr. Emery's estimate, 30lb. of steam per hour is taken to furnish an indicated horse power in ordinary engines. Then the horse power transmitted will be 120 W.

Diameter of main in inches.	Steam-gauge pressure.	Weight of steam conveyed.	H.P. transmitted by main.
	lbs. per sq. in.	lbs. per sec.

These figures are, necessarily, rough values. But they show that with steam very large amounts of power can be transmitted, without sensible pressure loss, through mains of moderate size.

LECTURE VI.

Distribution of Power by Gas and by Electricity.

Distribution of Gas for Power Purposes.—The distribution of gas for power purposes involves nothing new or untried. Coal gas is manufactured on an enormous scale, and distributed widely over extensive town districts. In the United Kingdom there has been expended on capital account in gas undertakings a sum of £60,000,000. The amount of coal carbonised annually is 10,000,000 tons, and the quantity of gas manufactured is 98,000 million cubic feet. If there were a demand for gas for heating and power purposes, there is no likelihood of failure of ability to supply and distribute it. Coal gas is already in many towns used on a considerable scale for heating and motive power. Mr. Trewby, the president of the Institute of Gas Engineers, estimates that, in the London district alone, there are 70,000 gas cooking and heating stoves and 2,500 gas engines.

Gas distribution has one distinctive advantage over compressed air or electricity distribution—namely, that the manufacture is carried on continuously through the 24 hours, the fluctuations of demand being met by storage, which is neither difficult nor expensive.

There is no reason to think that the cost of ordinary lighting gas is so high as to preclude its use on a considerable scale for power purposes. Taking the cost of lighting gas at 2s. to 3s. per 1,000 cubic feet, and the consumption of a gas-engine, on an ordinarily varying load, at 26½ cubic feet per hour per horse-power, the cost of the power for gas, exclusive of interest on the gas engine, comes to £8 to £12 per horse power per year of 3,000 working hours.

But the cost at which lighting gas is sold includes interest on a vast network of mains and the loss due to leakage over an extensive area. This part of the cost is not fairly chargeable against gas used for power purposes. In an installation for power the system of mains would be far simpler than in a distribution for lighting. With a comparatively few consumers taking comparatively large quantities of gas at a steady rate throughout the year, all the interest and depreciation charges would be smaller than those incurred in a distribution of lighting gas to a multitude of comparatively small consumers. It appears that the cost of the manufacture of coal gas, including coal, wages, and petty stores, is about 10d. per 1,000 cubic feet. Probably 18d. per 1,000 cubic feet would allow sufficient margin for profit and cost of distribution to power consumers in a manufacturing quarter not unfavourably distant from the generating works. But at that cost per 1,000 cubic feet the cost of the power would be only £6 per effective horse-power per annum. The charge for interest and depreciation on the motor plant and for wages would not add to this more than £3, making the total cost to the consumer £9 per effective horse power per annum.

Central Electric Lighting Station at Dessau.—This station, where the motive power is produced from gas engines worked with lighting gas, has been sufficiently successful to show that such a method of obtaining power is commercially possible. The station

(a) Not carburetted. (b) Carburetted.

installation consists of two two-cylinder (Otto system) gas-engines of 60 h.p. each, one single-cylinder engine of 30 h.p., and one of 8 h.p. The group of engines work to about 160 effective horse-power. Directly coupled to these are dynamos of corresponding power. The 8 h.p. engine is used for daywork and for starting the larger engines. The jacket water is cooled by air coolers and used over again. There are 1,076 square feet of cooling surface. An injector, worked by pressure-water from the town mains, circulates air through the coolers. The water consumption is thus reduced to five gallons per horse power hour for all purposes.

In an electric station, gas-engines have the advantage that they can be started and stopped when required, and have no stand by losses like those of steam boilers. At Dessau, a large accumulator battery is used for storing energy when the engines supply in excess of the demand, and restoring it in hours of small demand. The efficiency of the battery on the average of the year is 79 per cent. About 52 per cent. of the whole supply passes through the battery, so that the waste of current due to the battery is about 11 per cent. of the total yearly supply.

The average gas consumption of the motors is 26½ cubic feet per effective horse-power hour. Motors of varying power were adopted with an idea that they would best meet a varying demand. The constructors of the station now think that the accumulator battery renders this unnecessary, and that motors of a larger and uniform size would be more economical. They claim, as advantages of a gas plant compared with a steam plant, that less space and less water is required; that there is absence of smoke and danger of explosion; and that gas stations can be distributed more easily over the area to be supplied.

Distribution of Natural Gas at Pittsburgh, U.S.A.—A remarkable case of distribution of gas for heating and power purposes has been in operation at Pittsburgh.* The natural gas has entirely taken the place of coal in manufactories and for domestic heating in a district where coal is exceedingly cheap. Coal could be obtained at Pittsburgh for 4s. to 5s. a ton, and coal slack at 2s. to 2s. 6d. a ton.

The natural gas was met with in boring for oil, and was first used to raise steam for the oil pumping engines. At 18 miles from Pittsburgh an enormous outburst of gas occurred, which, for five years, was allowed to burn to waste. Then a company engaged to take it a distance of nine miles to Messrs. Carnegie's works. They were to be paid for the gas the value of its equivalent in coal until the capital cost of the pipes was repaid. After that, the gas was to be supplied at half the cost of its equivalent in coal. In 18 months the cost of the pipes was repaid, and the gas was then supplied at half the cost of its equivalent in coal. It was then conveyed into Pittsburgh and still greater distances. When Mr. Carnegie described the operations, there were 11 gas-mains, of 6in. to 12in. diameter, conveying gas to Pittsburgh.

The largest well discharged 30,000,000 cubic feet per day, and other wells half that quantity. At the wells the gas had a pressure of 200lb. per square inch; and at Messrs. Carnegie's works, nine miles distant, the pressure was 75lb. per square inch. This gave rise to difficulties from leakage, and it was found desirable to reduce the pressure in the pipes in towns, and even to place ventilating pipes at every joint in the mains, leading the leakage above the level of the street lamps. In using natural gas one fireman can manage boilers developing 1,500 h.p.

Other Gas Supplies for Heating and Power.—A cheaper gas than lighting gas can be manufactured for heating and power purposes. 1. So called "water gas," obtained by injecting superheated steam through incandescent anthracite or gas coke. Such gas has a volume of about 26 cubic feet to the pound, and develops about 7,373 thermal units F. per pound. 2. Dowson gas, made by passing air and steam through incandescent coal or coke. This gas contains a large amount of nitrogen, with the hydrogen and oxide of carbon. Four volumes of it are about equal in calorific value to a volume of lighting gas. It develops 160 thermal units per cubic foot. With anthracite at 13s. a ton, Dowson gas costs about 2d. per 1,000 cubic feet, exclusive of interest and depreciation on plant. 3. Mr. Thwaite has proposed for power purposes a gas of about 12 c.p., obtained by mixing lighting gas and producer gas. Such gas can be manufactured for 4d. per 1,000 cubic feet, and could be distributed and sold profitably for 16d. per 1,000 cubic feet. Its calorific value is little lower than that of lighting gas.

* See a paper by Mr. Andrew Carnegie on "Natural Gas," read before the Iron and Steel Institute.

The preceding table (A) contains data about various qualities of gas.

(*To be continued.*)

COMPANIES' REPORTS.

HOVE ELECTRIC LIGHTING COMPANY, LIMITED.

Directors: Colonel A. J. Filgate, R.E., chairman; Colonel H. Wood, C.B., vice chairman; Harold A. Hoare, Esq.; Carleton F. Tufnell, Esq.; John Wilkes, Esq.

First report of the Directors to be presented at the annual general meeting of the shareholders at the Town Hall, Hove, on Tuesday, December 12, 1893, at 3 p.m.

The Directors have pleasure in submitting their first report, and in congratulating the shareholders upon the success which has attended the operations of the Company to the present date. By the terms of the contract with the Hove Commissioners, approved by the Board of Trade, it is stipulated that the first annual balance-sheet of the Company shall be made up to the 31st December, 1893, but under the articles of association, a general meeting of the Company must be held in each year, when accounts made up to the latest convenient date have to be presented to the shareholders. With the view of complying with this latter requirement, the Directors now lay before the shareholders a balance sheet and profit and loss account made up to the 30th September last, duly audited, and which they propose shall be considered merely as an interim statement, to be superseded early next year by the accounts up to the 31st December next, prepared in the form required by the Board of Trade. It will be seen from the accounts attached to this report that the result of working up to the 30th September, after debiting to revenue a proper proportion of the administration charges from the 1st January, when the lighting was practically commenced, is a debit balance of £264. 10s., a result which, in a new enterprise, must be considered as satisfactory. Since about the middle of September, the working account shows a steadily increasing net profit each week, and the balance of the debit of the profit and loss account on 30th September has since been reduced considerably, and the Directors have every reason to anticipate that this balance will soon disappear. The contract with Messrs. Crompton and Co., Limited, was sealed on August 19, 1892, and by the 28th November following a temporary station had been erected, wherein were installed the necessary plant and machinery, a considerable length of permanent mains had been laid in culverts and casing, and the supply of electric current to the public was commenced, and has continued ever since without interruption. Since that date, the mains have been extended in various directions to meet the public demand, until the total length now laid exceeds 6½ miles. The erection of the permanent station by the contractors is rapidly approaching completion. A number of houses and buildings connected up to the Company's mains is 82, and, including the arc lamps and sockets, the number of lamps attached to the system is equal to 6,169 of 8 c.p. The applications for the light are steadily increasing, and it is confidently expected that the Company will soon be doing a large and remunerative business. From the station report of the 23rd November, the net profits of the Company, after providing for all administration and other charges, amounted to £18. 15s. for the week. It will be observed that on the 30th September last, the Company had issued 3,290 shares, and a few more have since been taken up, but the large amount due to contractors and others makes it a matter of urgent necessity that further capital should be obtained forthwith. The Directors have appointed Mr. Robert Payne (chartered accountant) to be the auditor of the Company, and it is proposed that he shall submit himself for re-election at the general meeting to be held early next year.

Balance sheet, Sept. 30, 1893.

Capital and Liabilities.	£	s.	d.
Authorised issue, 8,000 shares £5 each	40,000	0	0
3,290 shares issued at £5, £16,450; less arrears, £206	16,244	0	0
Loan from bankers	2,500	0	0

BUSINESS NOTES.

South Wales.—The towns of Aberystwith and Lampeter propose to introduce the electric light.

Great Northern Telegraph Company.—For the month of November the receipts were £21,600.

Western and Brazilian Telegraph Company.—The receipts for the week ended December 1 were £3,460.

Commercial Cable Company.—A quarterly dividend of 1¾ per cent., payable on the 2nd prox., has been declared.

Shanklin.—A committee has been appointed by the Local Board to consider the subject of electrically lighting the town.

Direct Spanish Telegraph Company.—The receipts for the month of November were £305 more than for the corresponding period.

Cuba Submarine Telegraph Company.—The receipts for the month of November were £38 more than for the corresponding period.

Eastern Telegraph Company.—The receipts for the month of November were £60,995, as against £60,491 for the corresponding period.

Blackburn.—It is proposed to erect new gasworks, and then the site of No. 1 gasworks will be used for electric lighting purposes.

Derby.—A joint sub-committee has been appointed from the Highways and Electric Lighting Committees as to street lighting by electricity.

Eastern Extension Telegraph Company.—For the month of November the receipts show a decrease of £604 as compared with the corresponding period.

Manchester.—The Lord Mayor, Aldermen Sir J. J. Harwood, Leech, Milling, and Councillor Southern have been appointed a special sub-committee in reference to telephones.

High Wycombe.—A committee of the Town Council has been nominated to deal with the provisional order, for which an application has been made to the Board of Trade.

The Blackpool Cars.—The Town Council have resolved to operate the tramcars by horses for a period of about three months, until some definite scheme can be pushed through the Council.

Charge of Embezzlement.—Mr. Henry Hunt, manager of the Taunton electric light works, has been arrested on a charge of forgery and embezzlement. He has been remanded until to-day.

Electric Railways in Japan.—A line is proposed to be built by American enterprise from Tokio to Yokohama, 30 miles long, connecting with a network of branch lines at both ends in these cities.

Swansea.—The Electric Lighting Committee of the Corporation were engaged on Tuesday in further considering the question of the electric lighting of the borough. Mr. Manville is advising the committee on the subject.

Tenders Accepted.—The following tenders were received for electric lighting and gasfitting at The Green Man, Bucklersbury, City: Christian, £104; Pragnell, £73. 10s.; Winn, £66. 15s. The tender of Mr. Winn has been accepted.

Bradford.—The members of the Gas and Electricity Supply Committee of the Corporation made their annual inspection on Tuesday of the premises used by the Corporation for the manufacture of gas and the generation of electricity.

Something Made Out of Telegraphy.—The value has been sworn at £83,965 of the personal estate of Mr. Henry Edward Weaver, late managing director of the Anglo-American Telegraph Company, and formerly secretary to the Electric and International Telegraph Company.

Sunderland.—In our last issue, in referring to the Sunderland tenders, it was erroneously mentioned that the amount of the tender of Messrs. C. A. Parsons and Co. for the whole of the work was £19,044. We are informed that the total sum should have been given as £14,052.

City and South London Railway Company.—The receipts for the week ending December 3 were £902, against £907 for the same period last year, or a decrease of £5. The total receipts for the second half year of 1893 show an increase of £178 over those for the corresponding period of 1892.

Eccles.—Alderman Kendall, who moved the adoption of the minutes of the Tramways and Electric Lighting Committee, at a meeting of the Town Council a few days ago, stated that the committee would at its next meeting discuss the advisability of taking steps to light certain portions of the borough with the electric light.

Lighting of Hammersmith.—The Vestry have decided that a scheme should be prepared for the electric lighting of the parish. Messrs. Morgan, Williams, and King, of Westminster, have been instructed to prepare, for the sum of 100 guineas, a report for the carrying into effect of the terms of the recently obtained provisional order.

Londonderry.—The Town Council have practically completed the electric light station. The contract for the electrical work has been carried out by Messrs. Siemens Bros. and Co. The Town Council, as will be seen from our advertisement columns, require the services of a chief engineer, an engine man and assistant, and a dynamo tender.

York.—It was mentioned at a meeting of the York City Council on Monday, that communications had been received from electric lighting companies inviting the Streets and Buildings Committee to inspect works and stations. It was stated that it was the intention of the committee to visit the lighting stations at the expense of the Corporation.

Huddersfield.—The School Board has adopted the electric light, which was brought into use at the offices for the first time on Monday. The Huddersfield Industrial Society have instructed the Managing Committee to light the premises of the central stores by electricity at an estimated cost of £1,600, provision being made for 550 lamps.

Bolton.—The Technical Instruction Committee of the Town Council have requested Alderman Miles, J.P., the chairman, to lay the foundation stone of the electricity buildings on Spa road, at a date to be fixed. They have likewise accepted the tender of Messrs. Edison Swan and Co. for switchboards, and that of Messrs. Crompton and Co., London, for accumulators.

Appointment Open.—Sir Edmund Hay Currie, of Currie Schools, Folkestone, requires a science master to teach physics only; must be a specialist with high honours at English or German university. The teaching comprises general and scholarship work and that connected with technical applications; practical work important; physical and electrical laboratories; exceptional opportunities for research; liberal salary.

Ruthin.—Mr. John Roberts in the course of the discussion on the formation of the committees asked, at a recent meeting of the Town Council, whether the Electric Lighting Committee had been called. Certain instructions were given that a committee should be called and they had been neglected up to now. The Clerk said he wanted to call a committee. He had a lot of correspondence to put before the Council.

Appointments.—Mr. Cuthbert Moore was recently appointed electrician on board the P. and O. steamship "Ganges." Mr. D. Bergin has been nominated electrician in the White Star Line. Mr. W. C. Thomson has been engaged as second engineer to the Westminster Supply Company, Eccleston-square station. All three qualified themselves as electrical engineers under Mr. Ronald Scott, M.R.I., M.I.E.E., Acton-hill, London, W.

Dudley.—In moving the adoption of the report of the Streets and Gas Committee, at a meeting of the Town Council, Alderman Bagott referred to the question of the electric light. He remarked that out of 60 towns in respect to which applications had been made for orders for the introduction of the electric light only four had put them into operation, the other 56 remaining dormant and watchful, which was a policy he recommended the Council to adopt for the present.

Hastings.—The Roads Committee of the Town Council have received an application from the Electric Light Company, Limited, on behalf of Messrs. Barrance and Ford, for permission to put up a projecting outside removable electric lamp at their premises at Claremont, and they recommended that the application be granted. The committee have also received other applications, which, together with the first-mentioned, have been granted.

St. Helens.—A sub-committee (comprising Aldermen Cook, J. C. Gamble, and M'Kechnie, and Councillors Dixon Nuttall, Beecham, and Forster) has been appointed to consider the provision of a supply of electricity within the borough, and the various methods suggested from time to time for enriching the illuminating power of the gas without increasing the cost. The St. Helens Town Council decided on Wednesday to apply to the Board of Trade for a provisional order to supply electricity for public and private purposes.

Swindon.—Tenders are invited by the New Town Local Board by the 11th inst. for the following: (1) The supply of gas, oil, or electric light to and lighting and cleaning of all lamps within the district of Swindon New Town for one year, commencing January 1; (2) the supply of gas, oil, or electric light only for all lamps within the district for one year, commencing January 1; (3) for the lighting and cleaning of all lamps within the district for one

year, commencing January 1. Tenders are to be delivered to Mr. H. Kinneir, clerk, Public Offices, Swindon

Salisbury.—Electric light installations have recently been put up on the premises of Messrs. S. Parker, Laming, and M. Parker, of Catherine-street. The current is obtained from a Tyne dynamo, driven by a 6½ h.p. gas-engine. Outside Mr. S. Parker's and Mr. Laming's establishments there are two 1,000-c.p. arc lamps. On the opposite side of the street Mr. M. Parker has three lamps of 200 c.p. Overhead wires connect the two sets of lights. The interior of each place of business is lighted by a number of 16-c.p. lamps. The installations have been carried out by Messrs. Roger Dawson and Co.

Aberdeen. The governors of Robert Gordon's College have approved the report of the Education Committee, who stated that they had before them the remit from the quarterly general court in regard to the question of the electric lighting of the college, with special reference to the proposals at present under the consideration of the Town Council for lighting the city by electricity. In view of the fact that the area adopted by the Town Council included School-hill, it was agreed to consult the official in charge of the works as to lighting the college buildings and the school of art from the Council's mains.

Lighting at Notting Hill.—The Highways Committee of the London County Council reported on Tuesday that two notices had been given by the Notting Hill Electric Lighting Company for mains across Campden-hill-road and along a part of Bedford-gardens, and for mains in Campden-hill-road and a short distance in Kensington High-street. The committee recommended that the sanction of the Council be given to the works referred to in two notices on condition that the company give two days' notice to the Council's engineer before commencing the works, and that the boxes be of a pattern approved by the Council.

Scenic Theatre.—The interesting display that was made by Messrs. Siemens Bros. at their little model theatre in the Crystal Palace Electrical Exhibition gave rise to an amount of eagerness on the part of the public everywhere to see the show and the similar device erected at the Chicago World's Fair has proved even more of a success. "After the fair is over," the model has now been moved to San Francisco, where, at the Midwinter Exposition, the energetic Western Electric Company (who secured the American rights of the arrangement) are continuing to give the public at large a liberal and interesting education in the possibilities of artistic and effective electric lighting.

Lighting in Oxford-street.—The Highways Committee of the London County Council reported on Tuesday that the St. James and Pall Mall Electric Light Company had given notice of intention to lay mains in Berwick-street from Oxford-street to Portland-street, with a crossing at Noel-street. The committee recommended that the sanction of the Council be given to the works referred to on condition that the company give two days' notice to the Council's engineer before commencing the works; that the covers of the street boxes be supported on 3in. York stone; and that before any street boxes are constructed the designs for and the proposed positions of them be submitted to and approved by the Council's engineer.

Chelsea v. London Electric.—In the Court of Appeal on Wednesday, before Lords Justices Lindley, A. L. Smith, and Davey, the case of the Chelsea Electric Supply Company, Limited, v. the London Electric Supply Corporation, Limited, was decided. On the 23rd of August Mr. Justice Wright made an order restraining the defendants in this action from laying down mains within a statutory area except in accordance with an agreement between the parties, and from that order the defendants appealed. Mr. Butcher, who appeared for the appellants, stated that the plaintiffs now admitted that the mains as laid by the defendants were in accordance with the agreement, and since the appeal was lodged the parties had come to terms. An order was accordingly made in the terms arranged.

Situations Vacant.—The Manchester Corporation require an experienced foreman, accustomed to dealing with workmen and competent to undertake all classes of cable work, bare copper strip, couplings, connections, attachments of leads and appliances. The Corporation also require several first-class vulcanised rubber cutters and jointers, well trained for coupling box and street tent work; and a person of good theoretical knowledge and previous experience of central-station work required as meter inspector, tester, and competent to do all connection work on consumer's premises, and to act as townsman generally. Application to be made to the Chairman, Gas Committee, Town Hall, Manchester, stating past experience, full details, and wages required for the vulcanised jointers per hour, and two other positions wages per week.

Charges for Current at Scarborough. The success which has attended the introduction of the electric light, and a desire on the part of the directors of the Scarborough Electric Supply Company, Limited, to encourage further extensions, have induced the Company to reduce their scale of charges. The charge per Board of Trade unit for electrical energy now varies with the number of units consumed in each quarter, in accordance with the following scale: Not exceeding 200 units, 6½d. per unit; exceeding 200 and not exceeding 400 units, 6¼d.; exceeding 400, and not exceeding 800 units, 6d.; exceeding 800 units, 5¾d. The charge for meter rent is 2s. per quarter for any number of lights not exceeding the equivalent of 50 8-c.p. 35-watt lamps, with 6d. extra per quarter for every additional 25 such lamps or their equivalent connected.

Derby.—Tenders are invited by the 16th inst. for the wiring, fittings, etc., for the various public buildings on the electric lighting area, for the Corporation—viz., Market Hall, Town Hall, Babington-lane offices, Full-street baths, weights and measures inspector's house, police stations, and fire brigade station, Derby. Specification and form of tender, containing plans, schedule of rooms, route of mains, etc., may be had on deposit of £1. 1s. (which will be returned on receipt of a *bonâ fide* tender), and particulars obtained on application to Mr. R. J. Harrison, borough engineer, Babington-lane, Derby. Tenders, endorsed "Wiring, etc., Public Buildings," to be sent to Mr. H. F. Gadsby, town clerk, Town Hall, Derby. The Rev. Dr. Macdonald, pastor of the Presbyterian Church, Greenhill, has undertaken to defray the cost of lighting that building by electricity. The cost will be about £120.

Fined for Defective 'Bus-Lighting.—Mr. Kingham, secretary to the London General Omnibus Company, was summoned at the Bow-street Police Court last week for allowing six omnibuses to be in a public thoroughfare after sunset without a light. Mr. W. Hicks, who appeared for the company, pleaded "Guilty" on their behalf. He explained that the vehicles complained of were fitted with the electric light, which answered admirably in the summer but proved a failure in the winter. The difficulty had been caused by an insufficiency of batteries which took about six or seven hours to charge. A new contract had now been entered into; the contractors would supply spare batteries, and would be liable to severe penalties if the light failed. Under these circumstances, he hoped the magistrate would impose a merely nominal fine. Sir John Bridge fined the company 1s. and costs in respect of each of the six carriages.

Town Refuse and Electric Lighting.—An interesting exhibition is now being shown at Halifax for the purpose of demonstrating the feasibility of generating steam for electric lighting, etc., with ashbin refuse as the only fuel. The installation, appropriate to the Northern Engineering Company, Limited, Parkinson-lane, consists of Livet's expanding flue steam generators (two-furnaced) capable of giving 300 h.p. when town refuse is burnt. The electrical plant comprises a powerful Parsons turbo electric generator, which energises a search light of 25,000 c.p., and a full complement of arc lamps. It is claimed that these steam generators, instead of simply destroying the refuse, utilise it to the fullest advantage by turning it into steam which can be used for a variety of purposes. This exhibition will prove not only interesting but also that it is possible to produce in any city the electric light at a low cost by simply burning rubbish.

Elmore's French Copper Company.—The creditors and shareholders of Elmore's French Patent Copper Depositing Company, Limited, met on Tuesday at the Holborn Restaurant before Mr. C. J. Stewart, official receiver. Mr. J. H. Duncan, the receiver for the debenture holders, reported that the property (excepting the Bellegarde land and the London assets) had been sold for £8,600 in cash, £60,000 in first mortgage French obligations, and 5,000 founders' shares. Further, that a scheme was being arranged whereby the debenture holders would accept payment in the French obligations; the claim of the Foreign and Colonial Company (who were the promoters of the French company) would be deferred; and the present unsecured creditors would become entitled to the first mortgage debentures of the resuscitated company. The Chairman pointed out that the Company expended £320,638 for the patents and upon the works, and yet the best offer that could now be obtained was £73,600, to be paid in cash obligations and founders' shares. Eventually, the meetings were adjourned to enable the scheme to be finally settled and submitted.

Electric Lighting Notices.—The following is a list of the applications made to the Board of Trade for the ensuing session: Aberdare Electric Lighting (P.O.); Bedford Electric Lighting (P.O.); Birmingham Electric Lighting and Power (P.O.); Brixton Electric Lighting (P.O.); Barrow-in-Furness Corporation Electric Lighting (P.O.); Chepping Wycomb Corporation Electric Lighting (P.O.); Camberwell Electric Lighting (P.O.); Chelmsford Electric Lighting (P.O.); Chesterfield Electric Lighting (P.O.); Collier Marr Moss Side Electric Lighting (P.O.); Crystal Palace District Electric Lighting (P.O.); Corporation of Clonmel Electric Lighting (P.O.); Guildford Electric Lighting (P.O.); Grimsby Electric Lighting (P.O.); Harrow Electric Lighting (P.O.); Lynton Local Board Electric Lighting (P.O.); Monmouth Electric Lighting (P.O.); Oswestry Electric Supply; Penrith Electric Lighting (P.O.); Plymouth Corporation Electric Lighting (P.O.); St. Austell Electric Lighting (P.O.); Swansea Electric Lighting (P.O.); Shrewsbury Electric Lighting (P.O.); Stirling Electric Lighting (P.O.); Wakefield Corporation Electric Lighting (P.O.); West Hartlepool Electric Lighting (P.O.); Yeadon Electric Lighting (P.O.).

Bankruptcy Proceedings.—At the Nottingham Bankruptcy Court the case of Mr. William Andrews, electrician, lately carrying on business at 118, Hanger Hill-road, Nottingham, was considered last week. Mr. Berryman appeared for the debtor. The Official Receiver said the examination had been adjourned from a previous Court in order that the debtor might deliver an account to the trustee of the money expended by him during the 12 months preceding the 29th of September, the date of the receiving order. The debtor had rendered an account, but it was not regarded by the trustee and himself as being satisfactory. It went very far from accounting for the sum of £900 which he admitted at his examination he had received within a period of two years, he believed, from the time of his bankruptcy. It was to be observed, however, that the debtor had not kept any books, and there seemed no probability of being able to obtain from him any account which would be more definite than the one before them. Therefore, the trustee was disposed, and he (the official receiver) was of the same opinion, to offer no objection to the debtor

passing his examination. The examination was then closed, debtor being allowed to pass.

Assessment of Electric Light Companies.—At a meeting of the City of London Union on Tuesday, Mr. Klenck drew attention to the electric lighting companies within the City and as to their assessment. It appeared that there were several of these companies carrying on business in different parts of London, but what more immediately concerned that Board and what he wished to know was whether the Assessment Committee of the City of London Union had proceeded to assess the electric lighting companies within the bounds or area of the City? Many of the traders and shopkeepers were complaining of having to pay such heavy rates, and he did not see why, if any revenue could be obtained from these companies, they should be allowed to go scot free, and the sooner they took cognisance of the presence and existence of these bodies in their midst, and at the same time made them contribute their quota to the City rates, the better it would be for the parochial exchequer and for alleviating the burden on the already heavily pressed ratepayers. Mr Odell, as chairman of the Assessment Committee, assured Mr. Klenck that the subject to which he had called attention was receiving attention.

Action regarding Bills of Exchange.—An action was decided in the Lord Mayor's Court on the 1st inst., in which Mr. Frank Urch sought to recover from Mr. M. Greenhill, an electrical engineer, of Mansion House-chambers, the sum of £23, the balance of principal alleged to be due upon two bills of exchange for £25 and £14 respectively, and the costs of a judgment paid by the plaintiff in respect of the said bills. Mr. Moses (instructed by Mr. Emanuel) was counsel for the plaintiff, and Mr. Sturgess (instructed by Mr. Edwards, for the defendant. The bills were drawn by the defendant and accepted by the plaintiff, and were discounted by a bill discounter named Talbot. Mr Talbot subsequently sued the plaintiff and defendant on the bills, and obtained a joint judgment against them, which had been satisfied by the plaintiff. Now the plaintiff sought to recover from the drawer his contribution of the total expense. The defendant declined to pay, firstly, because there had been no notice of dishonour, and, secondly, because the bills were drawn for the accommodation of the acceptor, who received the whole of the money less the charges for discounting. The jury found for the plaintiff, for whom judgment was entered, subject to a reference of the figures to the registrar.

Workington.—In a communication to a West Cumberland paper on the subject of water power, Mr F. Freeston says: "It is a well-known fact that our River Derwent is one of the quickest flowing rivers in England. And why allow her to deliver all her power into the mighty ocean without doing something for her guardian? Now just let me point out one place where a start can be made as a foundation for our noble river to help us—say, the millfield of Workington. Now for the work and distribution of power. First lay down very powerful turbines in order to give the river a chance. Say six at 4,000 h.p. each. Connect these turbines to very powerful alternating current dynamos. This power must now be distributed in order to benefit everybody. Lead electric cables—underground and overhead—to adjoining towns and villages, steelworks, ironworks and factories, railway and tramways, sawmills and flour mills, brickworks and collieries, farm houses and dwelling houses, main streets and turnpikes. Then those who want light will get it at a cheaper rate than gas. Then there shall be better health and more strength and prosperity. I may mention that electricity has developed so far even now that the people of Workington need not fear a trial. Let us make the public at large understand that there is someone willing to put his shoulder to the wheel in order to revive matters in Workington.

Coventry.—The Electric Light Committee of the Town Council have presented a report to the Council stating that they had called in Mr. A. H. Preece, of Westminster, to advise them, and submitted to him the tenders of the Brush Electrical Engineering Company, Limited, and Messrs. Hammond and Co. with John Fowler and Co. (Leeds), Limited. Mr. Preece reported that, after making certain additions to and deductions from the tenders, in order to reduce them to a common basis, that of Messrs. Hammond and Fowler was the lower by £278, and he recommended its acceptance, subject to certain small modifications to which Messrs. Hammond and Fowler have agreed. Mr Preece also recommended that, for the purpose of supplying current at times of light load a small plant of 15 kilowatt capacity should be added to the equipment of the station. The committee received an offer from Mr. Robert Hammond, associated with Messrs. Fowler in this matter, to retire from the contract to act as consulting engineer to the Corporation, at a commission of 5 per cent., the contract being placed with Messrs. Fowler and Co. at 5 per cent. less than the figure named in the tender. To this Messrs. Fowler are ready to agree. The committee recommend that this arrangement be carried out. The committee accordingly recommend that the tender of Messrs. Fowler be accepted, subject to their entering into a proper contract, and guaranteeing the efficiency of the generating plant to be not less than 75 per cent. at full load. The acceptance will also be subject to the sanction of the Local Government Board to the necessary loan. The amount of the tender as it stands is £8,843 6s. To this must be added the cost of trenching the streets, and of the small plant above mentioned, about £1,000 in all. There are also the purchase money of the site, the cost of buildings and the wages of the clerk of the works. While not anticipating that the estimate of £15,000 will be exceeded, the committee recommend that application be made for sanction to a loan of £20,000.

Lighting of Larne.—The principal business at the last meeting of the Town Commissioners was the consideration of tenders for the lighting of the town. The Chairman stated that they had received two tenders—one from the electric light company (the present contractors), and the other from the gas company. He would call on the clerk to read the tenders, and it was for the Board to decide in the matter. The clerk then read the tender and specification of the electric company, in which they offered to light the town with 11 arc lamps of 1,200 c.p. at £11 each per annum, six incandescent lamps of 32 c.p. £4 each per annum, 66 incandescent lamps 16 c.p. at £2 each per annum for the term of three years from August 1, 1894, from dusk till midnight in every day, from August 1 till the last day of the succeeding April, except that no public lighting shall be required for three days before and two days after the full moon in each month. In the event of any failure of the lighting of the town, the contractor will forfeit, in each instance, a sum equal to the cost of lighting during the said period of failure calculated at the price set out. The electric company were of opinion that the Commissioners might do well to purchase the electric light installation, spreading the payment over a term of years. The tender of the electric company was considered a very fair one by the majority of the Commissioners. The clerk drew the attention of the Board to the fact that the electric company quoted at so much per annum, and, perhaps, they would make an allowance for the three months that they would not be required to light. Mr. Fullerton and Mr. M'Quillan agreed with the clerk. The clerk then read the tender of the gas company. The majority of the Board were of opinion that it would be well to have a clear understanding with the electric company with regard to their price before deciding in the matter. The question was allowed to lie over till the next meeting.

Lighting of Bandon.—Mr. Wm. Foley moved, and Mr. J. Burke seconded, a resolution, at a meeting last week of the Town Commissioners, to the effect that Mr. T. Scanlan, solicitor, should take steps to oppose the Bandon Electric Lighting Company, Limited, in obtaining a provisional order. Mr. Foley said the promoters of the electric light company were invited to make their case before that Board on three or four occasions, and also before the ratepayers at the public meeting in the Town Hall, but had refused. Mr. Sherlock said he had no doubt that if met in a fair spirit by that Board they (the electric lighting company) would pay off their debentures of £1,700, and the effect of that would be to reduce the town rate. He (Mr. Foley) did not know what was meant by their meeting them in a fair spirit after their repeated invitation to come before them and show how their project could benefit anybody but themselves, except it was that they should hand over to their tender mercy, without question, the interests of the townspeople and ratepayers that they were sent there to preserve. Next year, when they would be under the Towns Improvement Act, they could borrow money for the purpose, and the Board of Trade, they (the Commissioners) being a local authority, would give them the necessary provisional order for the asking. The price charged for the electric light in Killarney was about equal to 5s. per 1,000 cubic feet for gas. There was a further reason why they should not hand over control of the lighting of the town to Messrs. Allman, the promoters of the new company, to be found in the danger there was to the prosperity of small towns of leading firms monopolising everything. In view of the consequences to the town of the hold the promoters of the electric company have over its destinies, it was their (the Commissioners) plain and bounden duty to prevent a single additional twist being given to the vice. It was no wonder that they found amongst the objects for which the electric company was established, one to promote another company to purchase themselves and their liabilities. The resolution was passed.

Lighting at Kensington.—The Highways Committee of the London County Council reported on Tuesday that the Board of Trade has, upon the application of the undertakers, revoked so much of the House-to-House Electric Light Supply Order, 1889, as relates to the area of supply specified in paragraph *h*, of the first schedule to the order, no application for the supply of electricity having been received from occupiers or owners of any premises within the area. The area referred to is situated in the north and north west portion of the parish of Kensington. The same committee reported that they had considered a notice from the House-to-House Electric Light Supply Company of intention to lay mains in Collingham gardens from Bramham gardens to Courtfield-gardens. Both high and low tension mains are proposed to be used, and the committee thought that in the interests of public safety the former should be laid at a lower level than the latter. They therefore recommend that the sanction of the Council be given to the works referred to in the notice upon condition that the company do give two days' notice to the Council's chief engineer before commencing the work; that the mains be laid under the footways wherever it is found practicable to do so, that the low-tension mains be placed 9in. below the underside of the paving, and those of high tension at least a foot lower; that no pipes of larger diameter than 6in. be used; that the street boxes be of the pattern approved by the Council, and that as an additional precaution against accident through defective insulation of the mains, each of the street boxes be provided with an inner as well as an outer cover, the two insulated from each other as far as practicable, and that the outer cover be efficiently connected to earth. The same committee reported that the Kensington and Knightsbridge Electric Lighting Company had submitted for approval a design for service boxes to be placed under the carriageways for use in cases where it is impossible to lay the mains under the pavement. The design appears to be satisfactory except as regards the cover plate, which the committee thought should be somewhat strengthened. They

recommended that the Council approve the design, on condition that provision be made for strengthening the cover-plate to the satisfaction of the Council's engineer.

Lighting at Hampstead.—The Finance Committee of the London County Council on Tuesday reported that they had considered the application from the Hampstead Vestry for the loan of £25,000 for electric lighting purposes. The Vestry proposed to provide a system of electric lighting for the parish, and as a commencement to erect on land belonging to them in the Finchley road the machinery and appliances for an installation for that part of the parish both for public and private purposes. The Vestry had submitted an estimate for the machinery and plant required, which amounted to £19,000 made up as follows: Boilers and accessories, £3,940; pipe work, £1,070; steam engines and dynamos for private lighting, £5,370, and public lighting, £770; switchboards, £720; mains for private lighting, £4,720, and public lighting, £110; arc lamps and posts, £700; and transformer sub-stations, £1,000. It appeared that some of the proposed mains were to be placed in the Finchley road, which is one of the disturnpiked roads, towards the maintenance of which the Council has to contribute, and before interference therewith the Vestry should obtain the sanction of the Council. This has not yet been applied for, but as at present the Vestry required only £5,000 to pay the contractors on account of work done, the committee recommended: "That, subject to the Council hereafter giving its written consent under seal to the borrowing, and subject to all necessary consents and evidence being furnished to the satisfaction of the solicitor of the Council, the application of the Vestry of Hampstead, for a loan of £25,000 towards defraying the cost of providing an electric light installation in the Finchley road for use in the parish, be granted, to the extent of £5,000, on condition that the loan be taken up at once, interest being charged thereon at the rate of £3. 10s. per cent. per annum, payable quarterly on the 1st of January, April, July, and October in each year, and the principal being repaid by equal annual instalments on each 1st October within a period of 30 years; that it be referred to the solicitor to take the necessary measures for completing the loan, and that the amount be advanced out of the Consolidated Loans Fund." The Council adopted this recommendation.

Chelmsford.—The Lighting Committee reported, at a meeting of the Town Council last week, that they had considered an order from the Board of Trade with reference to the placing of electric light wires under ground. They recommended that the wires in High street, Duke street, Tindal street, and King street, as far as the entrance to Messrs. Well's and Perry's timber yard, should be placed underground, but that in the remaining part of King street, Moulsham street, and Anchor-street the order of the Board of Trade as to placing the wires underground should not be enforced. They recommended the Council to accept the offer of the electric lighting company to renew the contract for lighting the public lamps at the expiration of the present contract upon the same terms and conditions as at present existed. The committee further reported that they had considered the provisional order for which the lighting company were applying to the Board of Trade. The order, if granted, would empower Messrs. Crompton and Co. to supply electricity in Chelmsford for 42 years, and to charge for every amount up to 20 units 13s. 4d., and for each unit after 20 units 8d. The committee saw no objection to the order, provided the price charged to consumers was reduced from 8d. to 6½d. for every unit over 20 units, and provided the company gave an undertaking that they would allow a discount of ½d. on every unit over 20 units if the money was paid within a month after delivery, and provided a clause was inserted giving the Council the option of purchasing the undertaking at the end of 21 or 31 years by valuation. The adoption of the report was proposed by Mr. Britton, and seconded by Mr. Osborn. Alderman Chancellor strongly objected to the proposal to give the lighting company the monopoly of supplying the electric light for 42 years. He proposed as an amendment that the matter be referred back to the Lighting Committee for further consideration. Alderman Morton said the provisional order would not prevent the Corporation from erecting plant of their own at any time, or from annulling their contract for the lighting of the town. If the Corporation were bound to have the town lighted by Messrs. Crompton and Co. for 42 years, then it would become a very serious matter for consideration. Alderman Duffield said they were asked upon the mere presentation of a report from a portion of the Council, without their having any opportunity of going into the details of the question or of understanding it, to bind the borough for 42 years. If they did that they would not be acting as sane, business like men. After further discussion, it was agreed that the whole question should be considered in committee by the whole Council. The Town Council have sealed the contract with Mr. T. H. P. Dennis to fix electric fire-alarm calls at the firemen's houses.

Exhibitors at the Smithfield Club Show.—Among the exhibitors at the Cattle Show, which closes to-day, at the Royal Agricultural Hall, Islington, N., are the following: Messrs. Robey and Co. of Lincoln, have on view portable engines, a compound engine and locomotive boiler combined, long stroke horizontal fixed engine, and a high speed vertical engine for electric lighting in mills, factories, etc. This engine is specially suitable where great power is required in a small space. It is designed to work with a high steam pressure, and may be arranged to run at such a speed as may be found most suitable for the work it has to do. When used for electric lighting it is mounted on a cast iron base plate, the other end of which carries the dynamo. The base plate is provided with lugs and adjusting screws, so that the driving-belt can be tightened without stopping the machinery. There are also shown an improved vertical engine, fitted with high-speed equilibrium governor, suitable for driving corn mills and barn machinery, and a Robey horizontal fixed oil engine. This works on the "Otto" cycle, and is mounted on a suitable base plate, containing a chamber capable of holding a week's supply of petroleum for working the engine. The oil used can be the ordinary unrefined heavy petroleum, which is said not to cost more than ¼d. per brake horse power per hour. At the stand of Messrs. W. H. Willcox and Co., of Southwark-street, S.E., is a display of general engineers' stores. There is a collection of best quality hand sewn leather belting, and of patent cork core packing, which is specially adapted for hydraulic purposes. Other exhibits comprise the usual stock packings, viz., self lubricative soapstone, red lead rope for joints, flax and hemp gasket, asbestos in various shapes and sizes, indiarubber valves, sheet, and washers, suction and delivery hose, etc. A speciality is the company's cylinder oil, and a good assortment is also made of general lubricating oils. There is shown for the first time the Penberthy patent injector. This obtained a medal at the Chicago Exhibition. The Farringdon patent pump is also on view, and a good general display is made of engineers' sundries, such as cotton waste, steam engine fittings and boiler mountings, lubricators, gauge glasses, screwing tackle, portable forges, grindstones, etc. The Britannia Company, of London and Colchester, show a 3 h.p. petroleum engine of the Roots type, for which they have acquired the sole right of manufacturing. This engine is operated by common petroleum lamp oil, and it is claimed that it is specially adapted for pumping and electric light purposes. There are also to be found at this stand a single geared milling machine for the use of engineers, brass finishers, etc., and a powerful shaping machine. Several types of gas engines, exhibited by other firms, are shown in operation, some of them driving dynamos for arc and incandescent lighting.

Lighting of Dewsbury.—The work of laying the mains is being executed by Messrs. Siemens Bros. and Co., who are carrying it out under contract with the Corporation. The Corporation took in the early stages of the project the advice of Mr. W. H. Preece, and the system about to be adopted is one he recommended. The electricity works will occupy the site of the old gasworks in Bradford road. The committee, which has the management of the gasworks as well as of the electric lighting scheme, is composed of the following gentlemen with the Mayor (Alderman Pyrah ex-officio, Alderman Robinson (chairman), and Councillors Archer (vice-chairman), Birkhead, Bullock, Fox, Howroyd, Knowles, and Whiteley. The amount of tenders for the complete scheme of lighting varied, the lowest being £14,636 (alternating currents), and the highest £25,050 (continuous current). The tenders were referred to Mr. Preece, who recommended the following to be accepted: Messrs. J. and H. Horsfield, Dewsbury, boilers, with an addition of £102 for pipe works, £3,000. Messrs. Crompton, steam pipes £758, condensers £1,176, steam dynamos £4,364, and switchboards £415, with a reduction of 5 per cent., £6,378; also arc lamps and posts, less the same discount, £983, and batteries £996, or a total of £8,357. Messrs. Siemens and Co., mains, including arc mains, £3,750, making a grand total of £15,107, which, however, will be reduced by £2,500 if arc lighting be excluded for the present, or a net figure of £12,607 to be expended, exclusive, of course, of engine and boiler houses. The engines to be supplied by Messrs. Crompton are of the Willans type. The mains have just been laid down in various streets and thoroughfares. The mains are on the three wire system. All this work of laying mains, etc., under Messrs. Siemens's contract is being carried out under the direction of Mr. Greene, their local manager. As to the engine and boiler houses, the first will be erected on the site in Bradford road in such a manner that extensions can be easily and economically carried out. The Corporation have issued a circular to the inhabitants in which it is stated that: "An 8 c.p. electric incandescent lamp may be taken as equivalent in lighting power to an ordinary gas burner of the usual size—that is, one consuming four cubic feet of gas per hour. Electricity will be sold at 6d. per unit; the cost of an 8 c.p. lamp is rather less than one farthing per hour. In London it is found that the average number of hours per annum during which an 8 c.p. lamp burns is under 300 hours. With electricity at 6d. per unit the average cost per 8 c.p. lamp is about 6s. 6d. per annum, including incandescent lamp renewals. The cost of wiring and fittings depends on the premises wired, the number of lamps installed, and the individual taste of the consumer. It may be taken as varying from 25s. to 35s. per lamp for shops, offices, etc., and from 30s. to 50s. per lamp for private houses."

Lighting of Swansea.—A Welsh paper, writing about the electric lighting of this town, says: "The Swansea Corporation is in possession of full powers—monopolistic powers—for the lighting of the borough with electricity. It will not be prudent for the Corporation to allow these powers to pass out of the hands of the municipality into the hands of any private individual or company, as was done long ago in the case of gas and gas lighting. Already a company has applied to the Board of Trade for a concession to them of the electric lighting powers of the Swansea Corporation, on the ground that the Corporation does not now make use of its powers practically. It is understood that other company promoters have similar intents upon the borough and upon its electric lighting powers. The fact that one company has thus applied to the Board of Trade will necessitate some clear and consistent declaration on the part of the Swansea Corporation as to whether it does, or does not, intend supplying the borough with the electric light. The Corporation has already declared that it will reserve to itself the power it possesses, and, in order to rebut the proposal of the above

commercial company, the Corporation will have to go before the Board of Trade and make good its own position. So far so good. We shall await with interest the issue of this important case. Meanwhile, the members of the Corporation and the burgesses as a whole have to face, and ought to face wisely and with foresight, the problems of the immediate future. It would seem to be too hazardous, as well as too big a venture for the Corporation at present to undertake the installation of electric lighting for the community. No doubt there are some other things that would work in with it, and be auxiliary to it, when this great determination shall have been arrived at. We shall want a mechanical destructor for the refuse of the community; and it is roughly estimated that such a destructor may easily be made the means of affording continuous mechanical power to the extent, say, of 40 h.p., day and night, at little cost. This 40 h.p., it is assumed, might be utilised as an instalment of the power necessary for the creation of electric light. These, however, are matters for further enquiry and clearing up. Meanwhile, the Corporation might, if opportunity properly offers, hand over its electric lighting powers, temporarily, but only temporarily, to a private company, under the most careful conditions and restrictions. The world is anxiously waiting for the discovery of some cheaper means or method than now exist for the creation of the force used in electrical illumination. As soon as this discovery is made, the electric light may be far cheaper, and far easier to work, than gas making and gas lighting, and thus the possession of monopolistic powers in the municipality will be a most valuable possession, which we, in our own day, or our successors soon after us, ought to enjoy the benefit and profit of."

Lighting at Dover.—A large number of gentlemen, interested as business men and inhabitants of Dover, assembled in the Council chamber in the Town Hall last week, at the invitation of the Brush Electrical Engineering Company, to hear an explanation with reference to the objects of the Dover Electricity Supply Company, Limited. The chair was taken by the Mayor of Dover (Sir W. H. Crundall, J.P.), who is the chairman of the new company, supported by Mr C. W. Bagshaw (vice-chairman and director), Mr. Sellon (director of the Brush Company), Mr Lawson (engineer of the Brush Company) and Mr W. Mowll (solicitor to the Dover Company). The Chairman introduced his brother directors, Messrs. Bagshaw and Sellon, Mr B. H. Van Tromp not being able to be present. He congratulated the company on receiving such a large amount of support. He reminded them that by a recent Act of Parliament the Corporation of Dover were given the opportunity of obtaining a concession for supplying electricity to the town. They did not see their way to enter into the business themselves, but they obtained the concession by means of a provisional order, with a view to transferring that concession to a company who would satisfy them that they had sufficient capital to instal the light in a proper manner, so that they would control it and see it started on the right lines. After a year or two of discussion the Corporation transferred the order to the Brush Company for a consideration, the Brush Company in their turn undertaking to form a local company. It had gone so far that the local company had been registered in the usual way and the board of directors formed with two representatives of the Brush Company and Mr. Bagshaw and himself as local directors. They hoped by next August or September that the tradesmen and residents of Dover would have the opportunity of supplying themselves with electric light, and they had also entered into a contract with the Corporation by which the sea front and one of the main streets would be lighted, with power to extend if they thought fit. Mr Sellon said the question of electrical lighting ought to be looked at from two points of view. First, that of the consumer, and secondly, that of the investor. These two points differed in some degree. The consumer wishes to be sure that it would be reliable, economical, and safe as regards life and property; and the investor wanted to know, over and above all, whether it was going to pay. As regards the question of cost, the speaker said that on an average it would cost from £1 to £1 5s. per light for the entire cost of fitting up. As to the cost of the illuminant, Mr Sellon said he found that from personal experience of the light in his own house for the past two or three years, it was from 20 to 30 per cent. higher than that of gas. But in spite of that, the greater advantage as regards health and convenience and preservation of furniture led to its adoption on an enormous scale. Alluding to the general position in Dover, he said that the company would commence operations in the course of the next month, and by July next there would be a station capable of supplying 5,000 incandescent lights, and they hoped to be able to supply 10,000 incandescent lights in 1895, and that they would be further enabled to extend this, as the company would have capital enough to be good for 20,000 lights. They estimated that the receipts would allow of a dividend of something between 7 and 8 per cent. Several questions were then asked and answered. It was stated that the street lights would be arc lights of 3,000 c.p., and that arc lights of 1,000 c.p. or less could be supplied for business purposes. The high tension system would be used for the mains in the street, but only low tension currents would be introduced into houses.

Lighting at Taunton.—The Electric Light Committee of the Town Council have considered Dr. Fleming's recommendations with regard to the extension of the electric lighting. The committee reported at a meeting last week that Dr Fleming states that it will be necessary at once to commence laying some of the underground lines. He proposes to get rid of the small house transformers, and to supply the central portion of the town from one common set of transformers, to be placed in sub-stations. The committee have had the cellar under the Municipal Buildings fitted up in order that it may be used as a sub-station for district No. 1, and they propose to lay a high tension cable from the electric light works to this cellar, in which will be placed two 30 kilowatt transformers and switches, and from there will be laid an underground three wire secondary cable, extending in each direction for 220 yards on both sides of the way down North-street, High-street, Fore-street, and East-street. The committee have obtained tenders (which have been submitted to Dr Fleming and upon which he reports) for a small alternator and exciter of 25,000 watts capacity, two 30 kilowatt (40 h.p.) transformers and switches, a quarter of a mile of high-tension cable, one mile of secondary distributing main, and a small high-speed engine for driving the small alternator. The committee recommended that the following tenders be accepted: Messrs. Laing, Wharton, and Down, for a small alternator and exciter, £284, and two 30 kilowatt transformers and switches, £261. 16s.; Messrs. Bunsted and Chandler, for a small high-speed 50 h.p. engine, £343; the British Insulated Wire Company, for a quarter-mile length armoured concentric cable, £81 5s.; and that the tender of the Fowler Waring Company for about one mile of triple concentric distribution cable be accepted, provided they will supply the exact length required at 7s. 4½d. per yard, and that an arrangement can be made with them to joint on all customers as required, lay and joint in the feeding mains, and generally to complete all the work in the first district, except opening and closing the ground; also to guarantee all the cable for five years, making good at their own expense all failures in ordinary work in that time. Councillor Potter, in moving the adoption of the report, said that one of the causes for the late electric light company's undertaking proving so disastrous was that at no time was the machinery employed at its full capacity. It was somewhat different now, as there were 1,250 lamps as compared with 486 previously, but that was not a continuous number. The number of lamps in use varied, some being used in the afternoon. All the tenders had been sent to Dr. Fleming for his approval, and the recommendations made by him were the recommendations of the committee, so that the report the committee now made was really not so much their own recommendation as it was of Dr. Fleming. Councillor Hammett seconded the motion. Some discussion then took place in regard to the great differences in the amounts of the tenders. It was ultimately decided to take the tenders *seriatim*. The first tender was accepted. With regard to the second tender Alderman Standfast moved that Messrs. Newton's tender be accepted, and one or two members present supported the idea, remarking that they thought the money should be spent in the town as much as possible. Councillor Potter mentioned that the tender of Messrs. Johnson and Phillips, which was the next one in price and the alternative one recommended by Dr. Fleming, was considerably lower than Messrs. Newton's tender, which he did not even mention. It was decided that providing Messrs. Newton could satisfy Dr. Fleming as to their instrument their tender should be accepted, and if not that of Laing, Wharton, and Co. should be accepted. The rest of the tenders were accepted, and the proceedings terminated.

Lighting in the City.—When the City Commissioners of Sewers met on Tuesday, Mr Burmester moved a resolution to the effect that the gas standards should be removed from the streets now lighted by electricity, and that the Streets Committee should carry this out. He said this was the legitimate outcome of the report of the engineer on electric lighting, which practically was to the effect that the electric lighting was satisfactory. The engineer reported that the majority of failures were not in groups, or for long periods of time, and that the total percentage of time the lamps failed was small. The electric light company thought the engineer ought in justice to have stated the actual percentages of failure, and they had supplied figures to the effect that the total number of hours during which the lamps were burning was 783,343, while the total number of lamp hours failure was only 374. The percentage of failure in lamp hours was thus ·047, or what was equivalent to one hour's failure in every 1,230 hours. He thought that justice ought to be done to the company by giving them credit for the way in which they had lighted the streets. The total amount of gas consumed on account of the failure of the electric light during the six months had cost the Commission 1s. 2d., whereas the engineer reported that the Commission were paying for maintenance of the gas lamps at the rate of £1,182 per annum. He thought the Commission would hardly consider it worth while continuing to pay this amount in order to burn gas to the extent of 2s. 4d. worth a year, to say nothing of the extreme inconvenience caused by the unused gas standards. After some discussion this motion was adopted. The question as to delays in the supply of current to private consumers was next considered. Mr Smallman submitted that a number of his neighbours were complaining that they had had their electric light fittings for some considerable time, but they had not yet had the current supplied. He asked whether there was no way by which the company could be stirred up to do their duty in this respect. The Chairman said that he had sent a letter he had received from one of his constituents on the subject to the electric light company, and he had received a reply from Mr. J. Cecil Budd, the secretary to the company. Mr Budd stated that the company were most anxious to supply all consumers and to avoid delay. As regards the preparations made at a great cost months ago by various firms, he could sympathise with them, but it must be borne in mind that this company never asked them to make such early preparations, nor have ever made promises to give them the light by a definite date. Continuing, Mr. Budd said: "They have to thank the irresponsible wiring contractors, with whom this company has no connection whatever, and who made all sorts of rash promises without authority in order to obtain the work. Now, as to the cause of the alleged delay. It must first be

borne in mind that we are a supply company, and cannot manufacture our own plant any more than the Commissioners can, but in order to prevent delay as much as possible, we have done everything that we can do ourselves, such as all building work, street work, etc. Then, again, our aim has always been to obtain the very best plant and cables. Sufficient generating plant has now been erected at Bankside to meet the demands of all applications for current lodged with us, and further machinery is being daily erected. When we come to the distribution plant, however, the contractors have not kept faith with us, and transformer equipment ordered by us over a year ago is not yet delivered The contractors allege all sorts of excuses for this strikes, non-delivery of proper raw material, and so on. Unfortunately, the equipments are as a rule patent articles, obtainable except from only certain firms We have now, however, made such arrangements as will overcome the transformer difficulty. You will also remember that it was only comparatively recently that we obtained sites for the 22 transformer stations of the area in which Mr. Ettlinger is situated viz., Milk street area was one of the last. As regards cabling, we are now drawing in cables at the rate of between five and six miles a week. While on this point, I do not think that it is understood by the Commissioners that the system of distribution we have adopted in the City is the latest and best - viz., with central transformer stations instead of small transformers in each house. This however, prevents us from supplying individual consumers dotted about in various parts of the City, as they seem to imagine can be done. Each transformer area must be complete in itself, and include all its own consumers. Naturally, we complete the areas in which there are most consumers, first leaving those in which there are but few to follow in rotation. Mr. Ettlinger's area is one of the latter, and I generally find that those people who are situated in an area in which there is least demand make the most fuss. As far as we possibly can, we are also putting in meters and house service boxes, and getting things generally all ready for joining up. The next areas we are dealing with are Lime street square, Rood lane, Warwick square, and Coleman street, and the others will be taken in order of number of applications, but, as far as I can see, all (except the outlying areas like the St. James's square, Redcross street, and Fetter lane ones) will be completed at different dates within, say, two months. The areas vary in size but an average area takes about 10 miles of cable. Some little delay takes place in joining the cables, as good jointers are scarce, and as it is one of the most important operations in the company's work, it would not be safe to employ other than fully-skilled workmen. It must not be forgotten that we are already supplying over 60,000 lamps, and have completed services ready to join up nearly 15,000 more. In conclusion, I must say I do not think the Commissioners fully appreciate the magnitude of the undertaking. We have expended over £700,000, and this should give a good idea of the amount of work which has been already carried out. I can assure you and the Commissioners that we are straining every nerve to make the private lighting of the City a success from every point."

PROVISIONAL PATENTS, 1893.

NOVEMBER 27.

22698. **Detector galvanometers.** William Routledge, 46, Low Friar street, Newcastle-on-Tyne.

22723. **Improvements in telephonic transmitters** Guillaume Arnaud Nussbaum 29, Ludgate hill, London.

NOVEMBER 28.

22765. **Multiple telegraphy** Jeremiah McCrath, The Elms, Melton Mowbray. (Complete specification.)

22817. **Improvements in electric meters** Hermann Aron, 6, Lord street, Liverpool

22856. **Improvements in printing telegraphs.** Robert Ashworth Fowden, Norfolk House, Norfolk street, London

22858. **Improvements in electric lighting and extinguishing apparatus for gas burners** Erik Orling, 45, Southampton buildings Chancery lane, London. (Complete specification.)

22863. **Improvements in and relating to dynamo-electric machines** Henry Harris Lake, 45, Southampton buildings Chancery lane, London (The Thomson Houston International Electric Company, United States. (Complete specification.)

NOVEMBER 29.

22885. **Improvements in and connected with electric generators and motors.** Montague Tabor Pickstone, 2, Todd street, Higher Broughton, Salford.

22912. **Improvements in electrodes and cells for secondary batteries or accumulators.** Edward Henry Wheeler, Walton-road, East Molesey, Surrey.

22956. **New improved electro-positive galvanic battery electrodes.** Carl Anton Johannes Hugo Schroeder and Heinrich Eugen Richard Schroeder, Whetstone House, Heslop-road, Balham, London. (Complete specification.)

22957. **Improvements in arc lamps** John Henry Wheat and Arthur Wheat, 323, High Holborn, London

22960. **Improvements in or relating to the method and means employed for controlling electrical devices from a distance.** Henry Wall Wilkinson and Leonard Penson, 433, Strand, London.

22959. **Improvements in or relating to apparatus for controlling transformers used in feeding electric current circuits.** Henry Wall Wilkinson, 433, Strand, London.

NOVEMBER 30.

23017. **An improved arc lamp.** Henry Robert Low and Frank Robert Brown, 1, Castle yard, Richmond. (Complete specification.)

23022. **Improvements in or relating to junction service boxes for electric conductors.** George Hinde Nisbett and James Bassnett Atherton, 6, Lord street, Liverpool.

DECEMBER 1.

23074. **Improvements in electrical switches.** William Paul Thoermann, 11, Great Ducie-street, Strangeways, Manchester.

23083. **Improvements in apparatus for recording electric currents** Hermann Aron, 6, Lord street, Liverpool.

23088. **An improved electrical indicating target.** George Henry Hodges and James William Ireland Hilliard, 4, St. Faith's villas, Fullerton road, Wandsworth.

23107. **Improved electrical games or toys.** Alfred Crespin and Oscar Felix Lehmann, 23, Southampton-buildings, Chancery-lane, London.

23116. **Improvements in electrical apparatus for indicating or indicating and registering variations in temperature or pressure or both.** Leo Sunderland, 46, Lincoln's inn-fields, London

23121. **Improvements in incandescence electric lamps.** James Yate Johnson, 47, Lincoln's inn fields, London. (Charles Henry Stearn, Switzerland.)

DECEMBER 2.

23133. **Improvements in electrical cranes or travellers** Henry James Coles, 89, Sumner street, Southwark, London.

23170. **Improvements in electrical transformers.** Leslie Bradley Miller and Maurice Walter Woods, 2, Gray's-inn road, London.

23182. **Electric station-indicator for railway waiting-rooms.** Adolf Jeenel 38, Alexandra-strasse, Berlin, Germany.

23211. **Improvements in electro-mechanical governors, and in the means of operating the same** Walter Thomas Goolden and Joseph Slater Lewis, 1, Queen Victoria street, London.

23221. **Improvements in sockets or receptacles and regulators for incandescent electric lamps.** Henry Harris Lake 45, Southampton buildings Chancery lane, London (Charles Albert Hussey and Charles Coulthurst Edey, United States.)

SPECIFICATIONS PUBLISHED.

1885.

5627. **Electric tramways and railways.** Smith. (Second edition.)

1890.

6083. **Electric propulsion of tramcars.** Gordon. (Second edition.)

6236. **Storage battery.** Jarman. (Second edition.)

1892.

18165. **Telephonic apparatus.** Lake (Noriega.)

21147. **Electric vehicles** Garrard and Blumfield

21693 **Electrical meter and recorder.** Feys and Lorwe.

22271. **Electric arc lamps.** Haseltine.

1893

257. **Insulating electric wires** Crompton and Dowsing.

5084. **Fastening electrical conductors, wires cables, etc.** Day.

8176. **Electrolytic apparatus** Hanbury.

10765. **Secondary batteries** Clubbe and Southey.

18894. **Standards of electromotive force.** Muirhead and Dearlove

18945. **Telephonic transmitter circuits.** Brookes. (Cousens.)

19024. **Trolley supports for electric railways.** Andersen.

NOTES.

Paris.—Extensions are being made in the municipal electric lighting district.

The Late Prof. Tyndall.—The body of the late professor was interred on Saturday at Haslemere.

Search-Lights.—A search-light has been arranged on the roof of Princess's Theatre, Oxford-street, by Mr. R. A. Scott.

Brixton.—A series of lectures on electricity is to be commenced at St. John's Institute, or Eltham House, Brixton, at the beginning of the new year.

Junior Engineering Society.—The members of this society on Friday last passed a vote of condolence with Mrs. Tyndall in connection with her recent bereavement.

Flexible Metallic Tubing.—It has hitherto only been possible to manufacture flexible metallic tubing up to 3in. diameter. Now, however, this kind of tubing is being produced up to 8in. diameter.

Lea Bridge Tramways.—The Lea Bridge, Leyton, and Walthamstow Tramways Company, who are asking for subscriptions for unissued capital, have powers to introduce electric or other power on their lines.

The Leeds Tramways.—A sub-committee of the Corporation Highways Committee has been appointed to deal with the whole question of the Leeds tramways, the transference of which from the present company is expected to take place shortly.

Engineers and Shipbuilders.—The third ordinary meeting of the North-East Coast Institution of Engineers and Shipbuilders will be held in the lecture-hall of the Subscription Literary Society, Fawcett-street, Sunderland, on Wednesday next at 7.40 p.m.

They Disliked the Bogies.—Some of the inhabitants of Brixton have complained of the noise made by the cable cars. Major-General Hutchinson is to report to the Board of Trade as to whether or not a further license is to be granted to the tramway company.

A Retrogressive Step.—The high price of gas due to the coal strike has caused the public lighting inspectors of Crowland, Lincolnshire, to decide to light the streets with oil instead of with gas. Why not make a forward step and introduce the electric light?

Shiplighting.—The "Forte," which was launched at Chatham Dockyard on Saturday, is a steel-protected, wood-sheathed, twin-screw, second-class cruiser. She will be fitted with three search-light projectors, and will be lighted by incandescent lamps, two dynamos being arranged in the engine-room.

Longton.—The Town Council have appointed a sub-committee to ascertain the powers of the Council as to the completion and working of the tramways in the borough, to make enquiries as to what is being done in other towns where tramways exist, and also to enquire as to the best method of traction.

Traction at Newcastle.—A scheme is under consideration for the adoption of cable trams in this town. A local paper discussed the question a few days ago, and compared the cost of working of the different systems of haulage introduced on the lines of the Birmingham Central Tramways Company.

New Method of Signalling.—A new system of signalling by day or night, designed for the use of the naval, military, merchant-marine, lighthouse, and life-saving services will be described at the Royal Service Institution to-day by Colonel Gouraud. A practical demonstration of the application of the system will be given.

The Devil's Dyke.—We note that the Cliff and Aerial Railway, Limited, has been registered with a capital of £20,000 in £1 shares, to construct and maintain an aerial flight or railway across the Dyke at Brighton. This matter was referred to in a previous issue, when, it will be remembered, it was mentioned that electricity will be used for motive-power purposes.

Conversazione.—The annual conversazione of the National Telephone Company took place in Glasgow the other day. It appears that the subscribers in the Scotch district of the company number 10,167, being an increase of 1,143 over the previous year. The mileage of the company in the district is 14,800, being an increase of 1,500 miles over the previous year.

The Government and Telephony.—The *Pall Mall Gazette* learns that there is no prospect of the agreement between the Post Office and the National Telephone Company being laid on the table of the House of Commons this session. Mr. Arnold Morley promised it some time in the autumn session, but it has not made its appearance, nor is it likely to do so before the House adjourns.

The Society of Engineers.—The fortieth annual general meeting was held on the 11th inst. at 17, Victoria-street, S.W. The chair was occupied by Mr. William Andrew McIntosh Valon, J.P., president. Mr. George Abraham Goodwin was elected president for 1894. The annual dinner was given at the Holborn Restaurant on Wednesday, the president, Mr. W. A. McIntosh Valon, J.P., occuping the chair.

The Liverpool Railway.—In the House of Commons last week Mr. Snape asked the Secretary to the Treasury whether the overhead electric railway at Liverpool had been assessed to the passenger duty; and, if so, on what terms. In reply, Sir J. Hibbert stated that no assessment had yet been made, and that the Board of Inland Revenue were in correspondence with the company on the subject with the view of determining the terms of charge.

The "Medical Battery" Company, Limited.—The official receiver has been appointed liquidator of this Company. Mr. Hannay resumed on Wednesday the hearing of the charges of conspiracy to defraud brought against Messrs. C. B. Harness, J. M. McCully, C. B. Hollier, and D. Towers. Mr. Thomas Terrell, one of the barristers for the prosecution, mentioned that he had about 400 witnesses to call. The hearing was again adjourned for a week.

The Joule Memorial Statue.—Lord Kelvin, last week, unveiled the Joule memorial statue, which has been placed in the Manchester Town Hall as a gift to the city. The work has been done by Mr. Albert Gilbert, and the statue forms a not unworthy companion to Chantrey's statue of Dr. Dalton, of whom Joule was, in his early days, a pupil. In an address delivered at the time, Lord Kelvin dealt with the discoveries and experiments of Joule.

Accumulator Works.—The Departmental Committee appointed by Mr. Asquith to enquire into white lead and the allied industries have issued their report. In regard to electric accumulator works, the committee recommend the adoption of respirators and overalls for mixers; the provision of gloves and aprons for rubbers; the provision of bath and lavatory accommodation, with a plentiful supply of hot and cold water, soap, nail-brushes, and towels.

Chesterfield and Midland Engineers.—A general meeting of the Chesterfield and Midland Counties Institu-

tion of Engineers will be held in University College, Nottingham, to-morrow (Saturday), at 2.30 p.m., when various papers will be open to discussion. The following papers will be read or taken as read: "The Hydrogen Oil Gas-testing Safety Lamp," by Prof. Frank Clowes, D.Sc.; "Automatic Expansion Gear in Use at Blackwell Colliery," by Mr. Maurice Deacon.

Royal Meteorological Society.—An ordinary meeting of this society will be held at 25, Great George-street, Westminster, on Wednesday next, at 8 p.m. Papers on the following subjects will be read: "The Great Storm of November 16th to 20th, 1893," by Mr. Charles Harding, F.R.Met.Soc.; "Rainfall and Evaporation Observations at the Bombay Waterworks," by Mr. S. Tomlinson, M.I.C.E., F.R.Met.Soc.; and "On Changes in the Character of certain Months," by Mr. A. E. Watson, B.A., F.R.Met.Soc.

Electric Lighting in Dublin.—The Postmaster-General was interrogated on Monday by Mr. Henniker Heaton as to whether he had entered into agreement with the Municipal Corporation of Dublin for the supply by them of the electric light to the General Post Office, Dublin. In reply, Mr. A. Morley stated that no such proposal was under consideration. Perhaps, he observed, the question referred to the new parcel sorting office in Amiens-street, where the Board of Public Works were proposing to provide the electric light.

Chamber of Arbitration.—The revision of the list of arbitrators for the Chamber of Arbitration of the London Chamber of Commerce is now in progress. The list already comprises the names of 1,400 gentlemen engaged in over 100 different professions, branches of trade, industry, etc., who have consented to act if selected by parties to references. Opportunity is now provided to add to the list. The following clause is recommended for insertion in contracts and agreements: "All disputes which may arise shall be submitted to arbitration under the rules for the time being of the London Chamber of Arbitration."

Risks (?) of Overhead Wires.—Minneapolis can hardly be called an unimportant city of the United States, and yet overhead trolley wires are there employed for tramways through the business parts of the town. The only accidents (or incidents) that have resulted since January 1, 1891, to date, have been—on the authority of the city inspector—three fires, with no damage resulting; four horses killed, and one man's leg broken owing to his fall from a pole on which he had received a slight shock. Taking into account the notoriously rough-and-ready way in which overhead construction is carried out in America, and the higher voltages there employed, there seems no reason why we need greatly fear the introduction of trolley wires in this country.

Electrical Communication with Lightships.—Mr. James Lowther asked the President of the Board of Trade in the House of Commons last week what actual progress had been made towards carrying out the recommendations of the Royal Commission with regard to electrical communication with lightships. In reply, Mr. Mundella observed that he replied to that question in answer to the hon. member for Dundee the previous week. He then stated that the work of connecting with the shore by electric cable the North Goodwin and the Kentish Knock light-vessels was being proceeded with as rapidly as practicable, and he hoped they would be completed during the present financial year. On Tuesday, Mr. T. W. Russell asked the President of the Board of Trade whether he would lay upon the table a return giving the correspondence between shipowners, Chambers of Commerce, Mr. T. R. Wigham, members of Parliament, the Commissioners of Irish Lights, the Trinity House, the Board of Trade, and others on the subject of lighthouse illuminants which had taken place since the issue of the last return on the subject. In reply, Mr. Mundella said that the correspondence was published up to February 24, 1893, and that which had ensued had not been such as to justify the cost incident on the printing and presentation to Parliament.

New South Wales Electric Club.—We have received a copy of the report of this club for the year ending September last. The council congratulate the members upon the success which the club has attained. Whilst the year has been a satisfactory one as regards the work of the club, the council regret to record losses of some of their most valued members by death. The council also regret to have to report a number of resignations, chiefly on account of members leaving the colony, but there is reason to believe that their loss will be made up by the accession of new members during the ensuing year. During the year 14 general meetings have been held, and papers on the following subjects were read and discussed: By Mr. P. B. Elwell, on "The Application of Secondary Batteries to Electric Traction"; by Mr. O. Haes, on "The Lighting of Railway Trains"; by Mr. O. W. Brain, on "Electricity as Applied to Mining"; by Mr. E. R. Dymond, on "Fire Insurance Rules as Applied to Electricity"; by Mr. A. F. Williamson, on "Central Stations"; by Mr. H. H. Kingsbury, on "Thirteen Years' Electrical Progress of New South Wales"; and, in addition, a discussion took place on "The Draft Code of Rules and Regulations for the Erection of Overhead Electric Light and Power Wires." The club were also invited to attend a paper read by Prof. Threlfall on "Some Problems Occurring in the Construction of Electromagnetic Reciprocating Mechanisms," before the Royal Society; also by Mr. T. D. Richards, on "Electricity as a Fire Risk," before the Insurance Institute of New South Wales.

The Pacific Cable Question.—We quote the following from the *Canadian Gazette*: "Mr. Sandford Fleming cannot fail to be encouraged by the reception given in the Australian colonies to his advocacy of a British cable across the Pacific. Queensland was, it will be remembered, one of the colonies to subsidise the French cable to New Caledonia; but, if we may believe Sir Thomas McIlwraith, until quite recently premier of the colony, this step was only taken in despair of getting a wholly British line. Speaking at the reception tendered to Messrs. Bowell and Fleming, Sir Thomas declared that he had always held that Australia ought to have subsidised a direct cable line to Canada, and that it should be done by the colonies interested at a price that would defy competition. Mr. Fleming would, he declared, have all possible help. All he desired was direct communication with Canada, and if it could be carried out by British capital, so much the better. Sir George Dibbs, the premier of New South Wales, the other colony which came to the help of the French company, gave Mr. Bowell equally emphatic assurances of sympathy. The New Caledonian line would, he hoped, wake up the British Government to the necessity of constructing a separate cable to Vancouver *viâ* New Zealand, Fiji, Samoa, and Honolulu; and he failed to see that the French cable should banish the demand for assistance in laying any such future Pacific cable through British possessions. The Intercolonial Conference which will, it is hoped, be convened at Ottawa about the middle of June next, and include representatives of all the Australasian colonies, will, we may hope, put these assurances of sympathy to a practical test."

The City Telephone Tubes.—The City Commissioners of Sewers had submitted to them last week a letter

from the City of London Electric Lighting Company asking the Commission to terminate the existing deadlock as to the telephone tube question by giving their consent as required by the Telegraph Act, 1891. The company first controvert the assertion that the tubes were laid simultaneously with the electric lighting mains without the knowledge of the Commission. With reference to the conditions which the Commission sought to impose on the users of the tubes—to grant a telephone service within the City at £8 per annum—the company were informed by the highest authorities that that was incompatible with an adequate return on the capital invested. No company had an exclusive right to supply telephone service in any part of the kingdom, for the Post Office authorities had repeatedly expressed their willingness to open exchanges if a certain number of subscribers asked them to do so, and, as they could carry out such a service more cheaply than a private company, any risk of a monopoly at once vanished. The existence of that powerful check against exorbitant charges would seem to render unnecessary a resort to exceptional measures. The company was erecting plant, etc., to supply 25,000 customers with electric light. If the revenue derived from telephone tubes be reduced to please 3,000 citizens, it could only be, it was submitted, at the expense of 25,000. In the meantime the tubes were lying idle, neither benefiting electric light users nor telephone subscribers. The existing companies, it was said, were every day putting numerous wires overhead which might, in many cases, be placed underground. The letter of the company is now under the consideration of the Commission.

A One-Volt Standard Cell.—In the *American Journal of Science*, Mr. H. S. Carhart considers this subject. The author employs a one-volt standard cell of the same form as the Clark standard. The tube contains pure mercury in contact with a platinum wire; on this is placed mercurous chloride paste, covered with zinc chloride solution. A cork diaphragm, with asbestos packing under it, is employed to keep the paste in position, and above it is placed more zinc chloride solution containing an amalgamated zinc rod; the whole is then hermetically sealed. The specific gravity of the zinc chloride solution necessary to give an E.M.F. of one volt at 13·7deg. is 1·391 at 15deg. The internal resistance of the cell is about 1,500 ohms, and it seems to suffer no permanent change by heating at 50deg. It is noteworthy that this cell has a positive and very small temperature coefficient; from 10deg. to 40deg. the temperature curve is approximately a straight line, and the E.M.F. is obtained from the equation, $E_t = 1 + 0{\cdot}000094\ (t - 15)$. Above 40deg. the curve rises and involves the third power of $t - 15$. The E.M.F. is observed to lag somewhat as the temperature falls; the hysteresis is, however, very slight, being equivalent to about 3deg. difference of temperature. The sign of the temperature coefficient of standard cells depends on the relative magnitudes and signs of the thermo E.M.F.'s at the two sides of the couple. These may be experimentally determined by means of an H-tube containing the solution and electrodes of the metal concerned, one limb of the tube is kept in melting ice, and the other in a bath at the required temperature. The E.M.F. set up is determined electrostatically, and is balanced against a standard E.M.F. Employing this method, the author has measured the thermo-E.M.F. of the voltaic series $Cu \mid CuSO_4, Cu$ between 0deg. and 50deg. as + 0·00073 volt, and has hence calculated the values for several other series, and compared them with the experimental values. The data given by Bouty, and by Chroustchoff and Sitnikoff (*Compt. Rend.*, 108, 937), would show the temperature coefficient of the author's cell to be small but negative. Bouty's thermo-E.M.F. for the series $Zn \mid ZnCl_2 \mid Zn$ is, however, too large; the author finds it to be 0·000584, a number from which the temperature coefficient of the new cell is calculated as practically identical with the value obtained experimentally.

The Board of Trade Draft Rules for Electric Traction.—In the short interval that has elapsed since the above regulations were issued by the Board of Trade for criticism by electrical experts, considerable progress has been made by the interests more particularly concerned with a view to undertaking not only individual but united action also, in the hope of effecting such changes in the rules, as drafted, that the reasonable development of electric traction shall be helped and not hindered. It is expected that the Institution of Electrical Engineers will set aside one of its ordinary meetings for discussing these regulations and the problems they involve; though, of course, no arrangements of this kind can now be made before the New Year. Yesterday afternoon the Municipal Associations formally began their criticism of the rules at a meeting of their delegates and officers to discuss this matter and decide upon some course of action. Finally, the third group of interests deeply concerned in the question—the Electrical Trades Section of the London Chamber of Commerce—instituted a similar movement on Friday last, when a sub-committee of well-known and influential men assembled to deal with the rules as might seem best to them. Amongst those present were Messrs. Crompton, Garcke, Stephen Sellon, R. P. Sellon, H. F. Kite, Carruthers Wain, etc.—all intimately connected with the electrical and traction interests—and a considerable amount of important business was transacted. After deciding upon an immediate course of action, the rules were discussed *seriatim*, and no lack of criticism resulted. On many points it was settled that further information should be sought from the Board of Trade, inasmuch as the rules were in a number of instances excessively obscure. The whole of Rule 6, with its sub-divisions, was referred to a special sub-committee in order to work out and compare the practical results which would follow if, in the first place, the rule were finally approved as it is, and, secondly, if it be amended in any one of several advantageous ways. Sub-section *a* of this rule is probably the most vague in the whole set; for a "separation" of the uninsulated return from earth can only mean that it shall be insulated, an obvious absurdity. Rule 14 is regarded as absolutely traversing the entire conclusions of the joint parliamentary committee, and if it be allowed to stand must inevitably postpone the development of electric traction to any extent whatever. It should be expunged altogether, as also should Rules 15 and 17, which are not only unnecessary but simply impossible to carry into effect. Further meetings will be held to discuss the rules in still greater detail, and conjoint action will then be taken with the other interests concerned, so that the fullest possible influence may be brought to bear upon the Board of Trade to modify the rules in the particulars finally agreed on.

The Electrical Purification of Sewage.—A few weeks ago we referred to the experiments being made in France with the Hermite system of purifying sewage by means of electrolysed sea-water. This method is being tried at Lorient, and an English commission has recently visited the town to inspect the working operations. A correspondent of the *Standard* was present with M. Hermite and Dr. Mark Armand Ruffer, who had journeyed from London to test the efficacy of the system for the British Institution of Preventive Medicine. The correspondent conducted Dr. Ruffer to the house where the electrolyser has been fixed up. On approaching the shed under which the electrolyser was at work they stepped

over a gutter running with almost completely colourless water. The liquid was entirely odourless, and seemed to have had the effect of cleansing the stone. M. Loire related that the old unused sewer of the former slaughter-house had for years been a fertile sources of epidemic diseases in the town. Very large sums of money had been spent in attempting to purify it, but till now everything had failed. At the very beginning of the experiments with M. Hermite's system he had flushed this sewer with the electrolysed sea-water. Its complete efficacy was, he affirmed, demonstrated by the result. The stench had entirely disappeared, and the masonry now looked as if the sewer had been restored. After leaving the Town Hall, the correspondent accompanied a large party of municipal authorities to the experimental works. Dr. Ruffer considers it his duty to urge a thorough practical trial of the system being made on a large scale in England. The Havre experiments, the correspondent states, have demonstrated that not only can the electrolysed liquid be manufactured in almost indefinitely large quantities, but that at the same time the application of this system, especially in a seaside town, would constitute a very considerable economy instead of adding to the expenditure of the municipality, as it has the advantage of saving all the water usually employed for the flushing of the nightsoil and sink-pipes of houses, as well as the much larger quantity employed in flushing the sewers and washing the gutters. At Havre, for instance, it is calculated that were M. Hermite's system to be adopted throughout the town the saving in water would not be less than 50 per cent. Everyone in the Normandy seaport seems to be in favour of generalising the application of the system. There are various indications that, not only in France, but in other countries the authorities are becoming alive to the importance of M. Hermite's system of electrical sanitation. In France, the municipality of Brest is at the present moment preparing a practical trial of the purifying method, and before the end of December the English colony at Nice will have an opportunity of witnessing practical experiments of the Hermite system, to be made, as at Brest, at the cost of the municipality. The trial at Nice will take place close to the Promenade des Anglais, and on a somewhat larger scale than that made here. At the end of the year, when the experiments at Nice have been organised, M. Hermite is to make a flying visit to Alexandria and Cairo, with the object of arranging for trials of his method in those Egyptian towns. As for Paris, it is becoming every day more probable that the Ile de la Cité will be made the scene of experiments on a large scale. Numerous other municipalities have written to M. Hermite with the object of making experiments with his system.

Physiological Effects of High-Frequency Electric Currents.—Mr. W. S. Hedley, M.D.Edin., in the course of a communication on this subject to the *Lancet* of the 9th inst., states: "Mr. A. C. Swinton's letter in the *Lancet* of October 14 will not only be appreciated by medical men as a valuable contribution to our knowledge of a new and difficult subject, but it will be accepted also as an indication that the electrical expert is willing to aid in the efforts of the profession to decharlatanise medical electricity and to reduce some at least of its problems to a question of sound physics. In referring to an article of mine which appeared in the *Lancet* of August 19, Mr. Swinton correctly states that the view therein adopted that high frequency currents are harmless mainly because of their small current strength is one previously put forward by him in the *Philosophical Magazine* of February last. It might also have been added, and no doubt would have been so had Mr. Swinton been aware of the fact, that before the appearance of the article in the *Philosophical Magazine* I, and before me the *Electrical Review*, had accepted this principle and referred to the 'whittling down' of current strength by the various transformations to which it had been subjected as a probable cause of this and many similar phenomena. This seems to be evidenced by an article on the physiological effects of alternating currents published in the *Lancet* of December 24, 1892, and by the pages of the *Electrical Review*. With the knowledge that exists of the surface transmission of high frequency currents along metallic conductors, Mr. Swinton's explanation of the power of such currents to light incandescent lamps becomes a very probable one; but when the human body becomes the conductor there seems to be no good evidence to show how such currents are transmitted unless (and this the present state of the question seems scarcely to warrant) the physiological effects claimed for them are accepted as a proof that they deeply penetrate the organism. This is a question in biological physics concerning which light and leading are still sought for. Mr. Swinton suggests a general law that, apart from some possible minor influences of frequency and abruptness of alternation, the physiological effects of electric currents are mainly proportional to their electrolytic effects. Other things being equal, this is probably true. But it seems to minimise the importance of other factors, and, taken as a law, to fall far short of the facts. As an instance those most obvious of all electro-physiological phenomena, the neuro-muscular effects that follow electric excitation may be cited. Putting aside for the moment the influence of current density, an old familiar experiment, in which a voltameter, an interrupting wheel, and a frog à la Galvani ('physiological limb') are connected up in a continuous-current circuit, may be considered. With the wheel at rest gas is disengaged and there is no visible muscular contraction. Once the wheel is put into motion evolution of gas nearly ceases, and the muscle is seen to strongly contract. In other words, unless a certain current is made and broken no visible muscular movement occurs. The mere passage of the current, be the electrolytic effect what it may, fails to produce visible contraction. Here motor reaction is proportional to the variation of the potential and to the suddenness with which that variation is made, as well as (no doubt) to the strength of the current used. But the question is not even so simple as this. With the 'interrupted Franklinic' current there is obtained a maximum motor effect with a minimum amount of sensation—viz., violent muscular contraction with practical immunity from pain. How does current strength help here? If smallness of quantity accounts for the absence of sensory effect, it can scarcely be invoked also to account for the marked presence of motor effect. Further, how does such a law cover the phenomena of 'make' and 'break' and the reversal of the formula in the 'reaction of degeneration,' or how does it account for those conditions of altered excitability known as 'anelectrotonic' and 'katelectrotonic'? In these cases there are varying physiological effects with the same current strength. How far the ordinary laws of physics and how far 'vital' endowments of living structure account for such phenomena have yet to be ascertained. It would appear that we must still content ourselves with the statement that the effects of electric currents on the body depend not only upon current strength, but on the mode in which such current strength is presented—*i.e.*, that physiological effects are proportional not only to the quantity of electricity, but also to its modality."

JOHN RENNIE.

Mr. John Rennie, M.I.E.E., was born in Ayr and educated at the Newton-on-Ayr Free Church School. Returning to Glasgow he entered upon business pursuits, taking advantage meanwhile of the excellent evening classes then carried on by the Glasgow Mechanics' Institute. He subsequently spent some years in the shipbuilding yard of Messrs. Barclay, Curle and Co., of Glasgow, where he acquired a practical experience of the various departments of engineering concerned in that industry. In 1876 he entered the University of Glasgow, following the courses in arts (specially physics) and engineering science, holding for three years a Thomson Experimental Scholarship. Towards the end of his term he became secretary and private assistant to Lord Kelvin (then Sir William Thomson), which position he held until 1890, when he received his present appointment, that of electrician to the Board of Trade. In this capacity he is acting as assistant to Major Cardew, electrical adviser to the Board of Trade, especially with reference to the equipment and organisation of the new laboratory recently established by that Department for dealing with electrical standards of measurement.

ELECTRIC LIGHT AND POWER.

BY ARTHUR F. GUY, ASSOC.MEM.INST. ELECTRICAL ENGINEERS.

(Continued from page 393.)

ALTERNATE-CURRENT WORKING.

In entering upon this subject the reader must be prepared to tolerate a little elementary mathematics, since the theory of alternating currents cannot be understood without. The whole subject, indeed, is one that calls for a fair mathematical knowledge, and every day the necessity of the study and examination of this branch of electricity becomes more and more compulsory to those who wish to keep pace with the development of electrical science. In direct-current work everything is so simple that those who have only had experience in that branch find themselves quite at sea when called upon to operate alternate-current plant, and this is not to be wondered at. A direct-current engineer has only to multiply his ammeter reading by the voltage of the circuit to obtain the electrical power that is going out; the alternate current engineer cannot do this. If an alternator is working at 2,000 volts pressure, and the current in the primary circuit is 40 amperes, the power given out is not $(2{,}000 \times 40)$ watts. Similarly if the alternating volts be divided by the resistance in ohms of the primary circuit, the quotient will not give the primary current in amperes. It is on this account that it is said that Ohm's law is not true for alternating currents, but it is perfectly true if applied in the right way, and all the other causes and effects are taken into account. There are more E.M.F.'s than one, and there are other obstructions to the current besides the mere metallic resistance of the conductors; they ignore the effects of self-induction and the lagging of the current behind the impressed E.M.F. Only a few of the rudimentary equations can be given here, and those who wish to enter into the subject should consult Dr. Fleming's work, entitled "The Alternate-Current Transformer in Theory and Practice"—the theoretical part is in Vol. I.

The nature of an alternating current has already been explained, and on referring back, Fig. 17 shows the two curves—the E.M.F., and the current that lags behind. It is necessary in dealing with this kind of work to know the value of both the E.M.F. and current at any instant—that is, at any stage of the periodic rise and fall. Suppose we have a coil of wire, as in Fig. 32, capable of rotation, and placed in a magnetic field whose strength is H; let the area of the coil be A, and let it make one complete revolution in the time T, then at any instant t the number of lines of force embraced by the coil are

$$N = H\,A \cos \frac{2\pi t}{T},$$

where the fraction $\frac{t}{T}$ determines the angle in degrees through which the coil has turned.

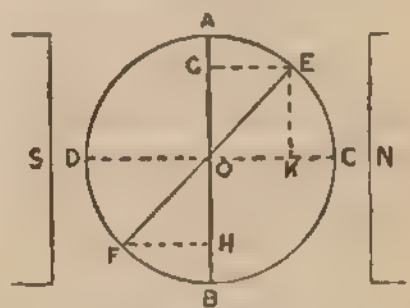

Fig. 32.

The slope of the curve at any point is obtained by finding the tangent of the angle which the curve at that point makes with the horizontal; evidently the angle cannot be greater than 90deg., because then the slope of the curve is at right angles to the horizontal—that is, it occupies a perpendicular position. The maximum value of the tangent is $M\frac{2\pi}{T}$, and when the cosine is diminishing, then the sine curve has a positive value, and *vice versâ*. If we suppose the number of lines embraced to be decreasing, we shall find that the time rate of change, or the E.M.F., E, produced, to be

$$E = \frac{2\pi}{T} A\,H \sin \frac{2\pi t}{T};$$

the expression $\frac{2\pi}{T} A\,H$ is, therefore, the maximum value of the time rate of change of N, and it is also interesting to note that if we have any quantity, N, undergoing variation according to a sine law, then the maximum value of rate of change will be

$$\frac{2\pi}{T} N.$$

The pulsating waves of an alternating current so closely resemble a curve of sines that the non-mathematical reader should establish for himself the following most important facts:

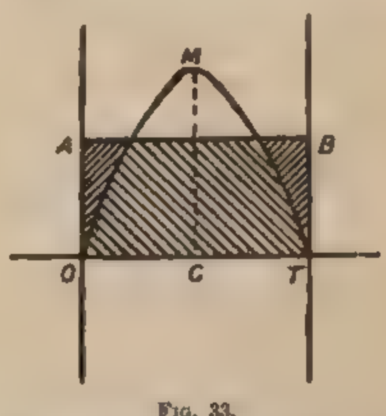

Fig. 33.

(1) The mean ordinate of a sine curve between values 0 and π is $\frac{2}{\pi}$ or $\cdot 637$ M, where M represents the maximum ordinate. In Fig. 33 the area enclosed by the sine curve, O M t, is obtained by multiplying the maximum height, M,

by the base, O t, and then by ·637. The area of the curve between the limits O and t is thus equal to the rectangular area, O A B t, since the ordinate, O A, is ·637 of M. Since the number ·637 is not far from 666, hence we may say that the time average of the fluctuating current is, roughly, about two-thirds of the maximum value of the current.

(2) In measuring an alternating current it is the square of the current that must be considered; hence the average given in (1) is not the true measure of the mean current, but it will be the square root of the mean square, expressed by $\sqrt{\frac{M^2}{2}}$ or $\frac{M}{\sqrt{2}}$, because the square of the maximum value is M^2, and the mean square is $\frac{M^2}{2}$; so that we have two mean values, the first being ·637 of the maximum, or the simple arithmetical mean, and the second being $\frac{1}{\sqrt{2}}$, or ·707 of the maximum, or the square root of the mean square. This last expression is now written thus, $\sqrt{\text{mean sq.}}$ for terseness. The difference between ·637 and ·707 is ·07, which thus shows that the simple mean is 10 per cent. below $\sqrt{\text{mean sq.}}$ Draw two sine curves, one of which is retarded by a small angle, ϕ, behind the other; multiply their ordinates together at every point, and take the mean value; increase the retardation, ϕ, and repeat the operation, and we shall find that we get a smaller result. Make ϕ = 90deg., so that the second curve commences at a quarter of a period behind the first curve, and we shall find that our result is now zero, and no work is done

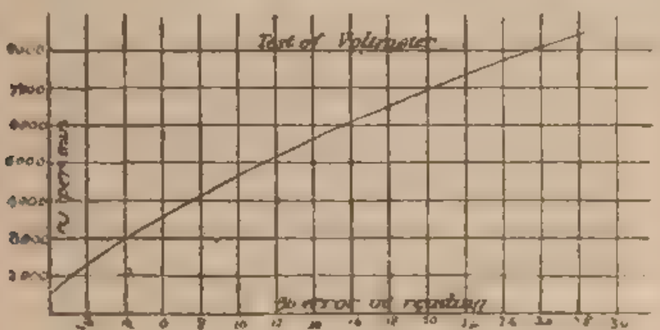

Fig. 34.

because the positive products exactly equal the negative products. If this operation be repeated for several values of ϕ, we shall find that the average value for a given value of ϕ is A B cos ϕ, where A and B are respectively the maximum ordinates of the two sine curves under examination. In an alternate-current circuit the current would be equally in phase with the impressed E.M.F., if it were not for the disturbing effect of self induction, which causes the current to be retarded, or to lag behind the impressed E.M.F. The following experiment illustrates how self-induction produces erroneous readings when ordinary measuring instruments which are made for direct-current work are used for alternate current work.

A horizontal coil, having a resistance of 1,158 ohms and consisting of 1,150 convolutions, has suspended at its centre a smaller coil, having a resistance of 65 ohms and 2,150 convolutions, the axis of the smaller coil being at right angles to that of the larger. The ends of the two coils are connected in series, and are then first joined up to a source of steady E.M.F. and the deflection of the small coil noted; the circuit is then broken, and the ends of the coils are joined up to a source of alternating E.M.F. of equal amount, when it is found that the deflection is much less; in fact, in one case, when the "frequency," or "periodicity," of the current was 260 per second, the deflection was 15 per cent. lower than the deflection obtained from a direct E.M.F. of equal amount. The accompanying curve shown in Fig. 34 shows the percentage of error observed when a voltmeter containing iron, and constructed for direct currents and steady E.M.F.'s, was used with alternating E.M.F.'s of various periodicity. With a periodicity of 133 per second, the reading on the voltmeter was no less than 26 per cent. lower than what it would be if the E.M.F. were steady, instead of being of an alternating character. The above experimental fact teaches us one very important lesson, and this is: that wherever there is any iron present in an alternating-current circuit, it will create self inductive disturbances. Therefore all instruments for measuring alternating currents, whether ammeters, voltmeters, or wattmeters, must be constructed free from iron.

An alternating current circuit may be one of two kinds—inductive or non-inductive. We will consider the latter kind first, as it is the simpler: a non-inductive circuit signifies one that has no self-induction, consequently the only obstruction to the current is the actual ohmic resistance of the conductors.

To measure the alternating current, we should take an electro-dynamometer, which will measure the $\sqrt{\text{mean square}}$ or $\frac{I}{\sqrt{2}}$, where I signifies the maximum value of the current; similarly, to measure the alternating volts, we should use a Cardew voltmeter, which will measure $\sqrt{\text{mean square}}$ of the impressed E.M.F., or $\frac{E}{\sqrt{2}}$, where E signifies the maximum value of the impressed E.M.F. Having now obtained both the current and the volts, the product of the two readings will give us $\frac{E\,I}{\sqrt{2}\,\sqrt{2}} = \frac{E\,I}{2}$, and this represents the mean power consumed.

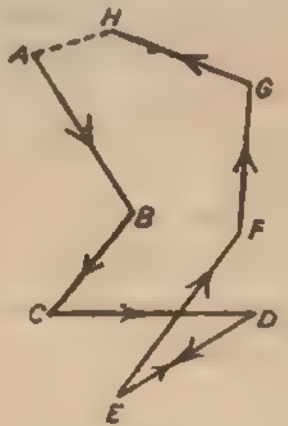

Fig. 35.

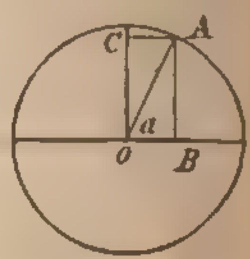

Fig. 36.

The above is true when both the E.M.F. and current are in step or in phase, but suppose that the current curve is retarded, and lags 60deg. behind the E.M.F. curve, then we shall have

$$\text{mean power} = \frac{E\,I}{2} \times \cos 60\text{deg.} = \frac{E\,I}{4}.$$

A graphical view of this is given in Fig. 35.

Suppose we have a number of forces acting on a point, it can easily be shown that if lines are drawn parallel to these forces, and proportional in length to the forces represented, and to some fixed scale, so that in direction and magnitude they may symbolise the several forces, then if all the forces are in equilibrium, the figure obtained will be a closed polygon, and if they are not in equilibrium, the figure will be open. For example, suppose A, B, C, D, E, F, G, H represent such a polygon, obtained from a number of forces, and open at A H, then the dotted line A H represents the resultant of all these forces. We shall now show that we can equally as well apply this to E.M.F.'s acting in a circuit. In an alternating current circuit we have usually three E.M.F.'s acting:

(1) The effective E.M.F., or the product C R.

(2) The E.M.F. due to self induction or inductance.

(3) The impressed E.M.F., which at any instant balances the other two.

Suppose we have a line, O A (in Fig. 36), revolving about a point, O; if O A represents to some scale the maximum value of an E.M.F. undergoing a sine variation, it will be

seen that we may represent the values at any instant by the projection of the line O A upon a fixed line, such as O C, which it will be seen is proportional to sin a. Now O A may represent the resultant of any number of E.M.F's. We may extend this, as in the case of the force polygon, and state that the projection of the resultant of any number of E.M.F.'s is the sum of the projections of its constituents.

An inductive alternating-current circuit is a much more complicated matter to deal with than the other, since we have to consider the disturbing effects of self-induction to obtain the power consumed in an inductive circuit. We must not multiply the $\sqrt{\text{mean square}}$ of the alternating current by the $\sqrt{\text{mean square}}$ of the alternating E.M.F., because the product would not measure the true mean power. The mean power at any instant of time, is obtained by multiplying the current at that instant by the E.M.F. at that instant; the same must be done for any and every other instant. We thus have a series of simultaneous results, and the mean value of this series will give the true mean power consumed. The product of $\sqrt{\text{mean square}}$ current and $\sqrt{\text{mean square}}$ E.M.F. is called the *apparent* mean power consumed in an inductive circuit; whilst the mean of the products of current and E.M.F. is called the *true* mean power consumed in an inductive circuit.

For a non-inductive circuit, or when the current curve is in step with the E.M.F. curve, the $\sqrt{\text{mean square}}$ current $\times$ $\sqrt{\text{mean square}}$ E.M.F. = mean product of current and E.M.F.; but, as explained above, this is not so with an inductive circuit, or when the current curve lags behind the impressed E.M.F. curve. In some cases the true watts may be only one-half what the apparent watts are.

In an inductive circuit we have to deal with self-induction, which may be defined as the E.M.F. that is produced by the varying current acting inductively on its own circuit. Where the current is a steady one—that is, of constant value—there is no effect apparent of self induction, because the magnetic field enclosing the current is invariable in strength; but immediately the current begins to

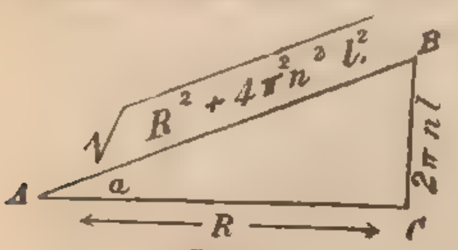

FIG. 37.

change and vary in value, like an alternating current, its magnetic field also begins to change in value, and when a conductor is surrounded by a magnetic field which is constantly varying in strength, an E.M.F. is set up which is opposite in force to the impressed E.M.F. of the circuit; thus in addition to the mere resistance in ohms of the conductor, there is a second obstruction to be dealt with. The obstructive effect which this counter E.M.F. has upon the current of the circuit is named the "inductance" of the circuit. Hence, we may say that a circuit has unit inductance when a current varying at the rate of one ampere per second will produce in it an E.M.F. of one volt, and this unit is named a "henry," or a "secohm," and is generally denoted by the letter L.

When the periodicity of the current is n ∿ per second, then the inductance is measured by $2\,\pi\,n$ L; where L is the said coefficient of self-induction, let the resistance of the conductors be R ohms, then the total obstruction to the current is $\sqrt{R^2 + (2\,\pi\,n\,L)^2}$, and this is named the impedance of the circuit, since it represents the whole resistance which the current has to contend against. Fig. 37 shows the relation between inductance and resistance, where resistance and inductance occupy two sides of a triangle, A C = R and B C = $2\,\pi\,n$ L, then the hypothenuse, or third side, A C, must equal the $\sqrt{\text{sum of the squares}}$ = $\sqrt{R^2 + 4\,\pi^2\,n^2\,L^2}$; hence the side A B = the impedance of the circuit. Suppose in a circuit having inductance whose coefficient is L, resistance = R, and impressed E.M.F. = E, that the maximum value of the current be I, then the product R I represents the volts absorbed by the metal resistance of the circuit, and these volts are named the effective E.M.F. The product ($2\,\pi\,n$ L) I will represent the E.M.F. due to the inductance of the circuit, whilst the product $\sqrt{(R^2 + 4\,\pi^2\,n^2\,L^2)}$ I will represent the impressed E.M.F. of the circuit. The angle B A C in Fig. 37 always defines the lag of the current I behind the impressed E.M.F.—that is, it measures the angle of retardation in phase—while its tangent represents the ratio existing between the inductance and resistance of the circuit. We can now give a rough formula for the adaptation of Ohm's law for alternating currents, which is—

$$\text{Current} = \frac{\text{impressed E.M.F.}}{\text{impedance}}.$$

Mathematically this may be expressed—

$$C = \frac{E \sin \theta}{\sqrt{R^2 + 4\,\pi^2\,n^2\,L^2}}.$$

The following experiments have been made by Mr. W. Brew, of the British Museum, and have been kindly supplied to the writer as illustrating some interesting results on the skin effect of alternating currents in conductors.

Skin Effect.—The method of experiment consisted in observing the increase in the force exerted upon a magnet pole reversing in synchronism with the alternate current, and placed just exterior to the conductor in which it was flowing. As the rate of alternation of the current was increased from zero upwards the current was forced outwards to the external layers of the conductor, and the force exerted upon the magnet pole was correspondingly increased.

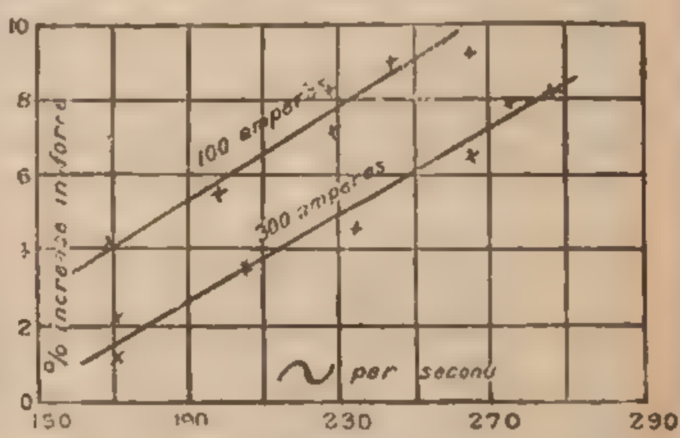

FIG. 38.

In one experiment, using a solid brass conductor 1in. in diameter, and passing various currents of a frequency of 200 through it, it was found that the force on the magnet pole had increased by about 20 per cent. of its original amount with continuous currents of equal value flowing in the conductor.

In another experiment a brass tube of the same external diameter, but ⅞in. internal diameter, was employed, and some of the results obtained are plotted in the accompanying curves, having for abscissæ the frequency of the alternating current and as ordinates the percentage increase in the force exerted upon the magnet pole over that due to a continuous current of the same numerical value. The upper curve was obtained with a current of 100 amperes at various frequencies, and the lower curve refers to a current of 300 amperes passing through the conductor under similar conditions.

The curves show us, amongst other things, that with a low current density the skin effect becomes more apparent than with a high one; also that after about 16,000 alternations per minute, or a frequency of 266 has been reached, the current rapidly becomes forced to the external layers of the conductor.

(*To be continued.*)

POLYPHASE ALTERNATE CURRENTS.

(Continued from page 543.)

It has been shown that, speaking theoretically, the field produced by two or three currents is constant, but we find as a matter of practice that it is not so. The presence of iron in the inductive system gives rise to hysteresis; and, conversely, the armature also reacts upon the field; alternating currents therefore can only be called more or less sinusoidal.

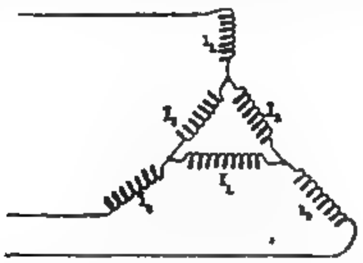

FIG. 15.

As a consequence the field varies from time to time above and below its theoretical value, and these variations are inversely as the number of coils in the field system. According to Messrs. Siemens and Halske's experiments, the variations were as much as 13 per cent. with only four coils, although they practically ceased when six coils were used with six currents displaced one-sixth period. In order to obtain a rotating field of constant strength, we might use a considerable number of alternating currents of different phases, but this would of course introduce many complications in producing and transmitting the currents. A simpler way is to vary the windings so as to increase the number of component fields, but not of the different-phased currents. To effect this we may employ any one of three methods:

1. A combination, see Fig. 15, of the two arrangements already mentioned—star-shaped and triangular. It is obvious that the currents circulating through the centre coils are displaced one-sixth of a period with respect to those in the outer coils. In a mixed winding of this kind

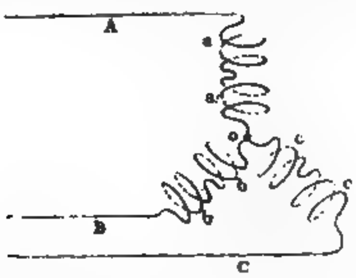

FIG. 16.

we have therefore six currents, each differing in phase by one-sixth of a period. By suitably arranging the resistances of the different coils we may obtain currents of the same strength.

2. Three alternating currents, A, B, C, of the same period and amplitude, but differing in phase by one-third of a period. According to this method (see Fig. 16), the coils *a a'* are wound in opposite directions, similarly with *b b'* and *c c'*. The result is the same as if the second coil in each case

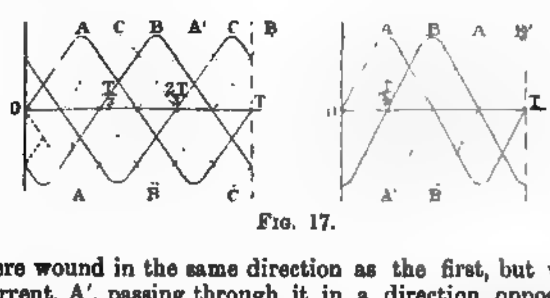

FIG. 17.

were wound in the same direction as the first, but with a current, A', passing through it in a direction opposite to that of A; and we have six currents differing in phase by one-sixth of a period, and succeeding one another in the *order* A C', B A', C B' (see Fig. 17). Similarly, we can get four currents displaced one-fourth period by the use of two currents displaced to the same extent.

In the case of a field produced by six currents, if H = the field strength produced by a current, A, passing through one of the six windings, it is obvious that the strength of the rotating field at each instant is 3 H, and that it makes one revolution per period of the alternating currents. The algebraic sum of these current strengths has a zero value throughout.

3. A still further step in this direction has been taken by Dobrowolski, who shows that when we superpose two currents of the same period, T, and strength, *c*, but

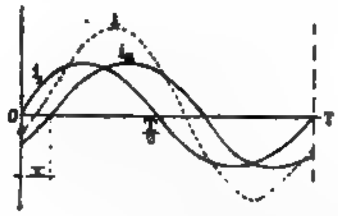

FIG. 18.

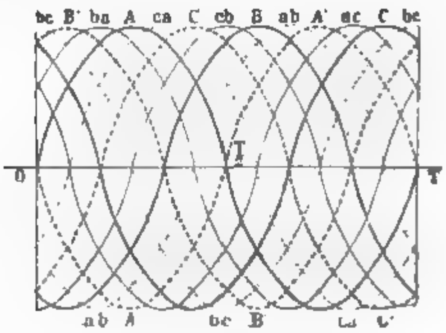
differing in phase by an interval, x (see Fig. 18), the current strength $C = 2c \cos \frac{x}{2}$. The first method above mentioned is in reality based upon the principle underlying this formula.



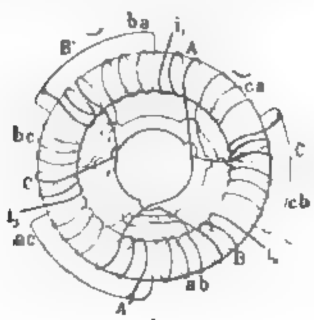


FIG. 19.

We can adopt as a combination of the two preceding methods the system shown in Fig. 19, where the windings are in opposite directions upon the coils—thus:

A and A'	B and B'	C and C'
a b and *b a*	*a c* and *c a*	*b c* and *c b*.

Their resistances are so arranged that the ampere-turns on each are identical. With only three currents displaced by a period of $\frac{T}{3}$ we therefore obtain the same effect as with 12 currents differing in phase by $\frac{T}{12}$. The resulting curves are shown in Fig. 19.

MULTIPOLAR FIELDS.

All the fields that we have so far examined (di-, tri-, and multiphase) have been bipolar. The alternating currents—whatever their number—produce a field of two poles, making one revolution per period of the currents. Under certain conditions, however, it is advisable to run more slowly—that is, we may aim at obtaining a field of m poles rotating with a speed $\frac{1}{m}$ of the current frequency. Of course, this result may be achieved by using two, three, or

more currents. In Fig. 20 are shown two examples of such arrangements, and they are sufficiently clear to need no detailed description beyond pointing out that one represents a diphase four-pole rotating field, and the other a similar field, but for triphase currents.

Instead of the windings shown—which are the simplest—we may have on each one of n sections a winding of the type already mentioned, and which will give with two or three currents the same effect (as regards a constant field) as might be obtained from four, six, or twelve currents.

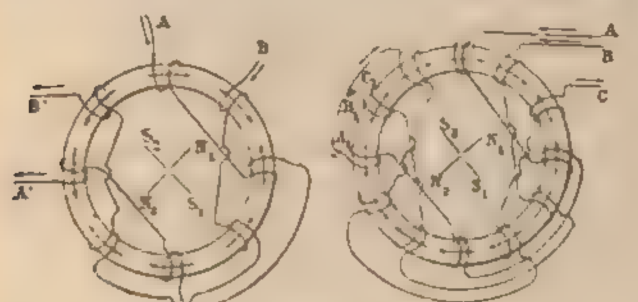

Fig. 20.

With reference to the strength of a multipolar field produced under these conditions, it is not easy to state in general terms its value at any particular instant. In drawing a curve to represent current strengths, it is evident that we have a multipolar field making $\frac{n}{m}$ turns per second (n being the frequency of the currents), but its strength is far from being constant.

The Armature.

Whichever method be employed to produce the rotating field, we use with it an armature whose windings are closed upon themselves. The rotating field develops in the armature currents which create a rotating magnetic field in the latter: this second field follows the motion of the first, and so makes the armature rotate, but at a speed considerably less than that of the first field. If the speed of the armature were equal to that of the first field, the flow of energy through its coils would be constant, and there would be no E.M.F. induced therein.

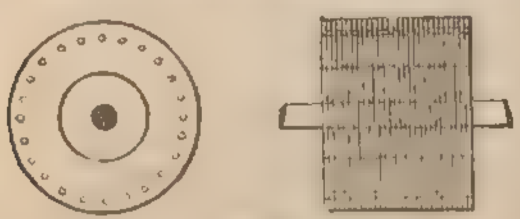

Fig. 21.

A winding is therefore chosen of such form as shall offer the least possible resistance to the currents due to the E.M.F. induced in the coils. The strength of the field produced by the coils is not increased by multiplying the number of turns (for an equal weight of copper), for the resistance being proportionally greater, the magnetomotive force, which varies with the ampere-turns, would remain the same. The only result would be to complicate the machine.

On the other hand, to employ a continuous winding of copper would prove disadvantageous by reason of the magnetic resistance, and in such a winding—as in a heavy iron armature—the currents would not necessarily take the course best adapted to generating a field. It is true that massive iron armatures have been used for small motors, but their consequent simplicity of design is hardly made up by the low efficiency.

In practice the construction shown in Fig. 21 is employed. The armature core, whether of drum or ring type, is built up of thin plates of sheet iron, well insulated in order to avoid Foucault currents. These discs are pierced with holes parallel to the axle, and drilled on a circular line near the outer circumference of the core. The armature conductor wires are passed through these holes, and thus constitute a winding which has the advantage of allowing a very small air-gap, and hence a reduced magnetic resistance.

In a bipolar rotating field, the conductors diametrically opposite are joined so as to form a complete closed loop; but there is another way of connecting them so as to save copper and give a more easy construction, both methods having the same result so far as the induced currents are concerned. In the second system of connection, the conductors are all joined together by two annuli or discs of copper, as shown in Fig. 22.

We may also wind the armature according to any of the methods already dealt with in discussing the field system.

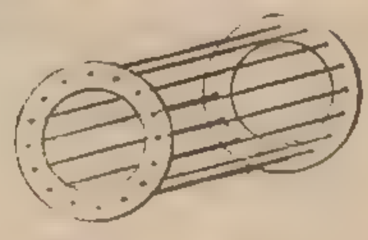

Fig. 22.

In such a case (using, for instance, triphase currents) the three free ends of the armature windings are led to three rings on the axle; and variable resistances may be introduced to prevent the current from reaching a strength too high for the conductors employed.

The Power Developed in a Motor.

If ω_1 represents the angular velocity of the rotating field, and ω_2 that of the armature, it may be shown that the total couple exerted is given by the equation

$$C = \frac{p\,\omega^2 N^2 l}{2\,r^2 + \omega^2 l^2},$$

where p = number of coils; r = the resistance of one coil, closed on itself; N = the lines of force due to the inductive field influencing the armature; $\omega = \omega_1 - \omega_2$, or the absolute value of the armature speed compared with that of the field; l is obtained from $\tan \phi = \frac{\omega\, l}{r}$. For the given machine, and for a fixed value of ω, it is evident that C is constant.

When ω tends towards zero—that is, when the armature rotates at a speed almost the same as that of the field—C also diminishes; on the other hand, C increases with ω. The maximum value of ω is given when $\omega_2 = 0$—that is, when the armature is at rest. The power developed is—

$$P = \omega_2\, C.$$

The calculation of a maximum value for P is rather long and complicated: the result is dependent upon the maximum value of ω, which again depends upon r, l, and ω_1—that is, upon the constructive details of the motor, and upon the frequency of the currents which pass into it.

Efficiency.

Losses Due to Resistance of Field System.—These depend upon the size adopted for the windings, and practically a calculation, similar to those carried out with other electrical machines, must be made. Questions of heat waste, conducting surfaces, etc., must all be considered; but all told, the losses in this direction for a well-designed machine will be quite insignificant, and should not in any case exceed, say, 3 or 4 per cent.

Losses due to Hysteresis and Foucault Currents.—These are proportional to the mass of iron employed, the magnetic induction passing through it, and the frequency of the alternating currents which form the supply. They may all be ascertained in a machine of given dimensions, etc., taking as a base for calculations the specific loss known to be incurred by transformers working under the same conditions as to frequency and strength of magnetisation; but it is not possible to arrive at their value in any general fashion.

It may, however, be noted that these losses will be the greater in proportion as the magnetic induction rises and the period of alternation diminishes. With regard to the

latter, we must distinguish between the field and armature. The period T_1 of the field is given by the equation :

$$\omega_1 = \frac{2\pi}{T_1};$$

that is, in the case of a bipolar-field system, in which the rotating field makes one turn per period. This period depends solely upon the currents entering the motor.

In the armature, *per contra*, the period of the currents is given by the equation :

$$T = \frac{2\pi}{\omega}.$$

Bearing in mind that $\omega = \omega_1 - \omega_2$, it is evident that T will always be much greater than T_1. To diminish the losses due to hysteresis and Foucault currents, it is advisable to reduce the iron in the field system to a minimum. This leads to the use of fields placed inside the armature, and of currents with long periods of alternation.

Loss Due to Armature Resistance.—The value of this loss is given by the equation :

$$\Sigma r c^2 = \frac{p}{2} \frac{\omega^2 N^2}{r} \cos^2 \phi.$$

The electrical efficiency in the armature is obtained from the following expression :

$$E = \frac{\omega_2}{\omega_2 + \frac{r}{l}};$$

but as we have already seen, $\tan \phi = \frac{\omega l}{r}$,

whence $$\cos^2 \phi = \frac{r^2}{r^2 + \omega^2 l^2};$$

so that whatever the speed, ω_2, of the armature may be, E will increase inversely as r and directly as l.

On the other hand, the greater ω_2 becomes, the more E tends towards unity ; but it must be noted that the power developed is a maximum when $\omega_2 = \omega_1 - \omega$, and that above such a value of ω_2 the power developed is reduced to zero when $\omega_2 = \omega_1$—that is, when the motor is running unloaded.

The Coefficient of Self Induction in the Armature Coils.

The magnetic flow produced by the currents induced in the coils is always normal to a plane making a given angle, ϕ, with the direction of the rotating field at the same instant. Resolving the flow due to each coil, in two directions, and summing the components, it is easy to show that the flow through any coil is given by the expression :

$$\frac{1}{R} 2\pi p \frac{\omega N}{r} \cos \phi \cos(\alpha - \phi) = l c,$$

where R = the magnetic resistance of the entire magnetic circuit.

Hence $$l = \frac{2\pi p}{R}.$$

(To be continued.)

ON THE ORIGIN OF THE FACTOR 4π IN THE EXPRESSION FOR THE MAGNETOMOTIVE FORCE OF A COIL.

BY A. E. KENNELLY.

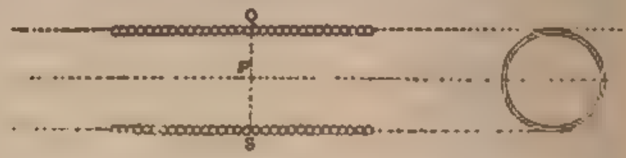
The magnetomotive force of a coil or solenoid is known to be $\mathcal{F} = 4\pi N C$ C.G.S. units, where N is the number of convolutions in the coil, and C is the current strength in C.G.S. units (of 10 amperes), so that, expressing the current strength in amperes by c, the formula becomes

$$\mathcal{F} = \frac{4\pi}{10} N c \text{ units.}$$

Since enquiries are frequently made concerning the origin and object of the coefficient 4π, we may here examine its *raison d'être.*

It may first be seen by two different methods of procedure that the intensity of magnetic flux within an indefinitely long, straight, hollow solenoid is $4\pi n C$ units where n is the number of turns in the solenoid per centimetre of its length, and then the main proposition will be immediately deducible.

Let r (centimetres) be the radius of the solenoid extending to infinity in both directions and partly represented in longitudinal and cross sections in the figure. The current, C may be supposed to be constantly circulating in every turn.



At any point, P, on the axis of the coil the intensity is due in some degree to each of all these turns. The greatest share is provided by the nearest turn, P Q S, immediately surrounding P. The intensity at P, due to this turn alone, is $\frac{2\pi C}{r}$. The share of intensity supplied by succeeding turns on each side diminishes steadily, and turns indefinitely remote obviously contribute an indefinitely small portion. The share contributed by any one turn situated at a distance, x, from P, measured along the axis, is $2\pi C \cdot r^2/(x^2+r^2)^{\frac{3}{2}}$.

The total intensity at P is the sum of all the terms of this type supplied by all the turns, or in mathematical language is the integral of the expression $\{2\pi C r^2 / (x^2+r^2)^{\frac{3}{2}}\} dx$ between the limits of positive and negative infinity in the variable, x. This integral is $4\pi n C = \frac{4\pi}{10} n c$, which represents the intensity at P in C.G.S. units, n being the number of turns per linear centimetre. This result is independent of the radius of the coil, and it can also be shown that the above intensity is not restricted to the axis, but has a constant value over the cross-section. In other words, the intensity is uniform within the solenoid, and equal to $\frac{4\pi}{10} n c$ units.

It is also evident that the flux density must be uniform over the cross-section of the long straight solenoid, from the fundamental principle that uniform flux density accompanies uniform flux curvature. The flux through the solenoid must follow straight lines parallel to the axis, except near the ends of the solenoid, and has therefore no curvature at any point of the cross-section. Its curvature being everywhere zero, its density is everywhere equal. On the other hand, the flux through a single turn of active conductor, or a very short solenoid, is nowhere parallel or uniformly curved, and the density nowhere uniform.

The same result can also be reached independently, as follows: The fundamental law of an indefinitely long solenoid, having unit cross-sectional area and n C current-turns per centimetre, is that it conveys a magnetic flux capable of producing at its ultimate extremities magnetic poles of strength n C. A unit magnetic pole is an ideal magnetic point source establishing unit intensity at a radial distance of 1cm. in every direction, and consequently all over a spherical surface of 1cm. radius, or 4π square centimetres in area. The unit pole therefore disperses 4π C.G.S. unit lines, so that the solenoidal pole of strength n C disperses $4\pi n C$ units, which flux must traverse the whole length of solenoid. But the interior cross-section being taken as one square centimetre, the density of this flux must be $4\pi n C$ units per square centimetre, or $4\pi n C = \frac{4\pi}{10} n c$ units.

Returning now to the consideration of magnetomotive force, we have the fundamental relation $\frac{\mathcal{F}}{\mathcal{R}} = \Phi$, where $\mathcal{R}$ is the total reluctance of the circuit in C.G.S. units, and Φ is the total flux, consequently $\mathcal{F} = \mathcal{R}\Phi$.

The reluctance of an infinitely long straight solenoid is all within it ; for although the exterior curved paths of returning flux must be longer than the interior straight path from pole to pole, yet the exterior path is infinitely wide, so that the reluctance of the external portion of the

magnetic circuit or air-gap between the poles is insignificantly small by comparison. In the case, then, of the magnetic circuit comprised by a long solenoid whose cross sectional area is unity, the reluctance would be one unit per linear centimetre, and if the very great length of the solenoid were denoted by X (centimetres) the total reluctance of the circuit would be X units to a high degree of approximation, and which would be exact for an infinitely long solenoid. We have also seen that the total flux would be $\Phi = 4 \pi n C$ units, and consequently

$$\mathcal{F} = X . 4 \pi n C \text{ units},$$

but $n X = N$ is the total number of turns in the solenoid, so that $\mathcal{F} = 4 \pi N C$, and the magnetomotive force is 4π multiplied by the current-turns, or $\frac{4 \pi}{10}$ multiplied by the ampere-turns on the circuit.

This rule for arriving at the magnetomotive force of an indefinitely long straight solenoid in which the air-gap reluctance is indefinitely small, applies immediately to a closed or endless solenoid—of the ring type—in which no air-gap exists. It also extends generally to any form of magnetic circuit, including or excluding iron. In general, however, the reluctance of such circuits and the intensity within them will be very complex, but any loop of conductor carrying a current of c amperes may be regarded as developing a separate magnetomotive force of $\frac{4 \pi}{10} c$ units.

INSTITUTION OF ELECTRICAL ENGINEERS.—Dec. 14

The annual general meeting was held at the Institution of Civil Engineers last night, when, in the first place, the usual formal business of reading and confirming the minutes of the last meeting was carried out.

The following gentlemen were balloted for:

Associate.—David Lowdon, Barry Graving Dock, Barry Dock, Glamorgan.

Student.—Henry Edward M. Kensit, care of Dr. Parker, Colne Valley, Rickmansworth, Herts.

After this formal business, the **President** referred in touching terms to the loss sustained by science in the death of Prof. John Tyndall. He mentioned that although the late professor was seldom seen at their meetings hardly one among them but was largely indebted to his writings for a knowledge of science, and none of the frequenters of the Royal Institution could ever forget the unrivalled powers of the late professor in presenting a scientific subject to his hearers so that the meanest intellect in the audience could understand. He concluded by proposing that the secretary send to Mrs. Tyndall a vote of condolence, expressing the sympathy of the society in her bereavement. This was seconded by **Prof. Hughes**, and carried unanimously.

The **Secretary** read the annual report, which stated that the number of members elected during the year had been greater than last year, the numbers being: Foreign members, 6; members, 18; associates, 101; students, 98; total 223. There have been 16 names transferred from the associates to members, and 58 from the students to associates. The Council had to regret that the losses during the year were heavy—namely, three foreign members, 12 members, 11 associates, and one student. The resignations, too, were numerous, consisting of five foreign members, eight members, 12 associates, and 11 students. The list of the Institution has increased by some 160 names, and about 40 candidates have been approved for the ballot at the first meeting next month. The Institution premium of £10 had been awarded to Mr. Sayers for his paper, but this year no other premium had been awarded. It was known to the members that Sir D. Salomons had generously increased his scholarship fund, hence the Council had been able this year to award two scholarships—to Mr. Riddle, of King's College, and Mr. Morris, of University College. Also a premium of £3. 3s. for the best student's paper had been awarded to Mr. Cooper.

Reference was made to the good attendance at the President's conversazione and at the annual dinner.

It was pointed out that through the generous hospitality, the members could meet in the rooms of the Institution of Civil Engineers, yet the time might come when it would be necessary to have a habitation of their own, therefore the Council contemplated setting aside an annual sum for a building fund, and had the matter still under consideration.

When the finances of the year came to be made up, it would be found that they were satisfactory, and a good surplus had accrued.

The **President** moved the adoption of the report, and called, evidently by pre-arrangement, on Mr. Ansell to make some remarks upon it.

Mr. Ansell ventured to ventilate a burning question, and one upon which a large body of members felt deeply. They had prepared a draft memorial, which was being signed for presentation to the Council. This memorial called attention to the desire of the members that all classes of members should be duly represented on the Council. In 1889, owing to an agitation, the Council was made representative, but as the members retired, representative members of a particular section were not re-elected. It pointed out that the telephonic interest, the private telegraphs, and the railway telegraphs were now not at all or insufficiently represented; and suggested that the twelve ordinary members of the Council should be constituted as follows: three to represent pure science, two the electric lighting industry, two public telegraphs, one railway telegraphs, one private telegraphs, one telephony, and two the manufacturing section; and that when any representative of any section retired, another representative of that section should be elected. It was suggested that 12 members of any section could propose a representative, and send in the name for the consideration of the Council by November 1 in each year. He went on to warn the Council that unless these interests were duly represented there would be a large secession of members. He pointed out that the magnificent institution that greeted them to-day was founded upon the action of the old-time telegraphist, and although the telegraphist had long since been passed in scientific knowledge, and perhaps in influence, to them a debt was owing, and they claimed representation. In referring to his own personal position, Mr. Ansell pointed out that since 1845 he had been actively engaged in telegraphic work, and was the sole remaining old-timer on the active list. Five men were still living, but not actively engaged, out of 84 who were in the thick of the fight in 1846. One friend had come to honour their meeting of that evening in the person of Mr. Wilkins, who had built the first telegraph from Thorpe to Norwich, using the old five-needle instrument.

The **President** interrupted the speaker, and said that possibly a majority of the members and of the Council agreed with Mr. Ansell, and suggested a committee of the memorialists to confer with the new Council on the subject.

Mr. Ansell agreed, and the report was adopted.

The next business was in giving various votes of thanks, which, although partaking of a formal character, are nevertheless fully recognised as expressing the full opinion of the members.

Prof. Fleming proposed the vote of thanks to the Institution of Civil Engineers for the continued use of their rooms, which was duly seconded and carried.

Mr. A. Siemens proposed the vote of thanks to the foreign secretaries, one of the best known of whom—Mr. Aylmer—was present. This was seconded by **Mr. Evered** and carried.

Sir D. Salomons proposed the vote of thanks to the hon. auditors, Mr. Danvers and Mr. Streb, which was seconded by **Prof. Hughes** and carried unanimously, as was that proposed by **Mr. Mordey**, and seconded by **Mr. Wright**, to give a vote of thanks to the hon. solicitors.

The **President** stated that the scrutineers had reported the house list of President, Vice-President, and Officers, as given in our last issue, duly elected.

The discussion on Prof. Forbes's paper was then resumed.

Mr. Ferranti referred to the submission to the Cataract Construction Company of designs, which, although they were not found satisfactory in the carrying out of the whole of the details, yet they formed a very good basis upon which to design a dynamo. He referred to the records of the Patent Office, where he had provisionally protected a method of oil insulation of the armature for conveying away the heat in the machine, but found that the method was wrong, and he did not endeavour to secure complete protection. He recognised in the design of the dynamo a feature of the C. E. L. Brown machine, perhaps the man who had had the most experience in that class of work for long distance transmission. He noticed the winding was of strip, and insulated with mica, that was the design sent in by Mr. Brown. He thought it was a very general practice among English engineers to circulate water continually in the jacket around the bearings. It would be effectual in this particular case if the water was continually on. He regarded the method of exciting in series anything but the best. Concerning the dynamo being built by the Westinghouse Company, he was surprised to see, after the failures and successes of high-tension work, that they had not gone in for more than 2,000 volts. There was a great difference between designing dynamos and building them, and also in getting together a collection of information in the world, and then without any previous knowledge of dynamo design, building and running, to fulfil great expectations. This was a point of the greatest difficulty in the Construction Company's scheme. He then dealt with the pressure of 20,000 volts, and compared it with the 10,000 volt current used at Deptford. The subway with high E.M.F. would, he believed, be a very hot place: 10,000 volts was bad enough, but 20,000 volts might be worse, and an accident might lead to a complete breakdown of the system. The subway might, perhaps, be the most unsatisfactory part of dealing with the question. He could not agree with the periodicity of 16·2 per second, even with 25 periods a considerable amount of lighting would be done, and the most practicable was by direct transformation from the high-pressure mains. The periodicity adopted by Messrs. Ganz—viz., about 40, was more satisfactory. It certainly rendered both arc and incandescent lighting possible, and was somewhere about the happy medium. He made some very stringent remarks on the manner in which the company had obtained designs from experts in different countries. This side of the question was most important. It was upon the work of the world that the undertaking would be carried out, but he did not attach any blame to Prof. Forbes in the matter.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months'	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

TRACTION.

The unknown is gradually being obliterated from the question of the cost of electric traction. In the early days of any industry, business must be transacted more or less from the basis of estimated cost. Then, after a practical attempt at work has been carried out, time is necessary to show the exact cost, and to take the matter from the region of fancy into that of fact. Electric traction is being developed in two ways—one as the motive power on what are practically railways, and the other to replace horse traction on tramways. There is a vast distinction between the two cases, and we are not sure but most people will agree that the railroad problem is the simpler of the two. Dr. Edward Hopkinson, in his lecture at Owens College, has given the cost of electric traction on the City and South London line at a fraction under 6½d. per train mile. The estimate of the contractors before the work was commenced led them to guarantee that the cost should not exceed 8½d. per train mile. We have to point out that the City and South London line was originally intended to be worked by cable, and probably its design would have been considerably altered had electric traction been determined from the first. Then, again, this was actually the first line of its kind, and however experienced constructors of dynamos and motors and the other paraphernalia of electric traction may be, it is absolutely certain that a second venture of a similar fashion would in some measure be better than the first. Experience must be a guide, and perfection is not obtained at the first trial. Hence, with a line designed from the first for electric traction, and with the improvements that experience will suggest, we should expect another line to be worked at even a less cost than 6½d. per train mile. It is estimated that with a quicker train service the existing line could be worked for about 4d. per train mile. Now, with the exception of this last estimate, which we should say is amply warranted by facts, the other expenses are facts, and cannot be gainsaid. They prove our contention that even now in many instances electricity is a better and a cheaper power than steam. It is not, however, so much on railways that our hopes for immediate development are directed as on tramways; though Liverpool has followed South London, and is amassing further facts to prove these views. But in England, at any rate, the tramway authorities are hard to move. There are good reasons in many cases for this, but we hope better reasons will prevail and bring about a great change. It is rumoured that Newport, Mon., which has lately decided upon adopting the electric light, the work for which is being carried out, will not be averse to the acquisition of the tramways and their extension. If there is any probability of such acquisition at an early date, it would be worth while to consider how far the proposed electric light station and installation could be modified so as to assist in traction purposes. Tramway work under conditions that could easily be designed and with a quick service, ought not to cost more than horse traction. This may be gathered

from the last report of the Birmingham tramways, although therein it is shown that electric traction cost them about sixpence per car mile more than horse traction; but we maintain this sixpence would about disappear if the conditions were, as they might be, greatly improved. All information bearing upon this subject is interesting, whether it be in the direction of railroad or tramway traction.

UNAUTHORISED NOMENCLATURE.

Elsewhere we reprint, or partly reprint, an article from our American contemporary the *Electrical World*, written by Mr. A. E. Kennelly. Now, Mr. Kennelly is a clever writer, and he knows it—hence is apt to presume a little more than is good for him, and certainly a little more than is good for the generality of technical students. The ruling powers of the *Electrical World* have placed themselves in an equally false position to that of Mr. Kennelly. Let us in the first place state our grievance, and in the second place state the rule which we think all technical writers and journals should follow. Mr. Kennelly, in the article referred to, has named certain units tentatively "gilbert," "weber," "oersted," and "gauss." He was not the first to use the term "gauss"—that use lies at the door of Prof. S. P. Thompson, who ought to have known better. The rule we think ought to be adopted by anybody desirous of naming a unit would be to bring their suggestion before the notice of some authoritative body representing the profession, and all use of new terms should be rigidly avoided till sanctioned by authority. When once a self-satisfied writer has started upon a voyage of discovering names, he assumes his superiority to all and sundry, and is persistent in advocating what tends more to the ridiculous than to the useful. Every unit is to be named, and the name, according to modern electricians, is to commemorate an individual of historical repute. It has been pointed out long ago that the number of units is limited, and the number of names, if not unlimited, will in the time to come receive additions deserving of longer and greater renown than most of those who have gone before and who have been thus honoured. In ancient days philology played its part in word-formation, and worse things might happen than if electricians should again turn for assistance to philologists; but these views have little to do with our immediate object, which is to enter an emphatic protest against the introduction into any article or book of unauthorised terms. We know at least of one society, all-powerful in its own sphere, that absolutely refuses to admit into its journal any unauthorised new term, or even an unauthorised formula. The society has carefully examined and recognised certain letters used in common formulæ to indicate certain things, and these, and these only, are admissible into papers read before the society or published in its *Transactions*. The result has been satisfactory. In this society, when a paper is read there is no need of explanatory sentences, and no difficulty in ascertaining the interpretation of the author's work. With electricians one introduces the "hop," another the "bot," a third the "gauss," a fourth the "oersted," "gilbert," and "weber," and so the ball goes rolling along till you might as well attempt to understand the ravings of a lunatic as the lucubrations of one of those ready writers. Scientific journals have their duty to perform in this matter, and they should refuse to allow the use of terms not sanctioned by some authoritative body, except, perhaps, as suggestions in correspondence. We intend to follow that plan, and exclude terms not internationally recognised, or sanctioned for the time being by the Institution of Electrical Engineers. The latter body ought to draw up—it started to do so some years ago—a scheme of nomenclature and notation which should guide contributors to its *Proceedings*. If the English Institution will not prepare a scheme we trust the American Association will, and compel its members to fall into line. We have long since given up hopes of English electricians taking an initiative except when the subject is one that appeals to the pockets or the glorification of individuals.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

SHUNTS.

SIR,—For a long time past I have had an uncomfortable feeling of want of accord with the explanation of the various text books as regards shunts. A book much admired in its day—Sabine, 1867—comes correctly, though somewhat inelegantly, to the conclusion that "the current in each of the 'branch circuits' is of the same intensity as it would be were the battery in circuit with that line alone, and that when the resistances of the lines are equal the currents circulating in them will be equal also." That would seem to be clear enough, and so simple as not to be mistaken. It assumes pressure at the ends of each branch equal and constant; hence the current in each branch is indicated by the formula $C = \frac{E}{R \text{ of that branch}}$.

Culley, 1878, defines *shunt* as "a wire connected across the terminals of a coil to divert a portion of the current."

Sabine tells me that the current in one branch is absolutely independent of that in any other branch—and it is; hence it cannot "divert a portion of the current," and Culley is wrong. I am fain to believe, however, that Culley's teaching is the accepted teaching, and Sabine's not so generally accepted, for

Gunn, 1890, says: "It is often desirable to send only part of the total current through a galvanometer. This is done by joining up a wire in multiple arc with the galvanometer, so that the current is broken up before it enters the galvanometer, and part goes through the wire and part through the galvanometer."

That is true; but if Sabine is right—and he is—why, just as much current goes through the galvanometer unshunted as when shunted.

Prof. S. P. Thompson, 1881, says: "Strong currents must not be passed through very sensitive galvanometers, for, even if they are not spoiled, the deflections of the needle will be too large to give accurate measurements. In such cases the galvanometer is used with a *shunt* or coil of wire arranged so that the greater part of the current shall flow through it, and pass the galvanometer by, only a small portion of the current actually traversing the coils of the instrument. The resistance of the shunt must bear a known ratio to the resistance of the instrument, according to the principles laid down about branched circuits."

According to Sabine, this statement is all wrong. Just

as much current goes through the galvanometer coil after as before the fixing of the shunt. The use of the shunt, as it were, only makes room for a proportional increase of current. Now, among this diversity of teaching, what am I to believe? My reading of Ohm's law—which, of course, may be all wrong; but as yet no one has shown me it is so—says that so far as current is concerned every branch circuit is independent of every other branch circuit, provided that pressure is kept constant. None of these teachers mention pressure, or E.M.F., or difference of potential, or whatever they like to call it. They leave me to infer—as I do infer—that in all cases they mean me to understand that pressure is constant; and if that is so, then no putting in of shunts can affect the current in the galvanometer. The formulæ for shunts, and much of the bother about them, is all fudge, and only perplexing to the student. I have spent many hours listening to rigmaroles about shunts, and many more reading about them, only to find I have lived in a fool's paradise, and that it is rubbish to talk about by-paths, or that the shunt takes a part of the current which would otherwise go through the galvanometer. You cannot put more or less current through a galvanometer or any other circuit except in one way—by increasing or decreasing the pressure acting. I am well aware that much that is taught about galvanometers is quite correct. I am merely declaiming at the waste of time and trouble I have undergone to be stuffed with information—principally for passing some examination or other—that turns out to be altogether misleading. I could give you extracts from a lot of other books telling me to use a shunt for fear of melting the galvanometer coils, but each and all attributing the effect to the leading away a part of the current through another path than the coils. Perhaps, Sir, you will put me right if I am wrong, and tell me whether the insertion of a shunt is for the purpose of carrying away, say, overflow current, or whether it merely opens up a new channel in which new current is generated in strict accord with Ohm's law.—Yours, etc.,

H. L.

[Our correspondent has fairly taken our breath away. Here is tilting in real earnest. Has he failed in some examination through some misunderstanding with the examiner? If so, we should advise a course of soothing powder; for kicking against examiners does not pay in the long run. They are like parsons, or the House of Lords, against either of which appeals are rarely or never countenanced. But there is much in what "H. L." says. Yet if we begin to criticise the varied statements in school books, we had better wind up all other business and restrict ourselves to that alone. He may, however, in this case accept as correct Ohm's law, which applies to every circuit, the current in the circuit being according to the formula $C = \frac{E}{R}$, so that if he puts one or one hundred shunts in parallel with the coils of his galvanometer by connecting each branch, say, with the terminals of the galvanometer, so long as the pressure acting between the terminals is constant the current through the coils will be absolutely invariable, and no shunt or by-path will affect it in the slightest. In fact, the paths are not shunts or by-paths—they are new paths, and to produce electrical phenomena in them new current is generated just as Sabine describes.—Ed. *E. E.*]

USE OF CONDENSERS.

Sir,—Our attention has been drawn to a recent issue, in which you give an abstract of a paper read before the American Institute of Electrical Engineers. At the conclusion of this abstract the authors are made to express their opinion that "The experiments with the condensers demonstrate the practicability of their use to diminish the line current in transformer circuits, and points to their more extended use as their manufacture is perfected and cheapened, not only in this, but also in other systems of alternating-current distribution." As the paragraph implies the non-existence of any practical condensers, we ask your permission to point out that we have ourselves been manufacturing condensers (under the Swinburne patents) on a commercial scale for the last two years, principally for Germany, and out of the total number supplied by us only one has been returned broken down. We think, therefore, we are fairly justified in claiming to have solved the problem of condenser manufacture on a commercial scale, price being, of course, merely a matter of demand. The Stanley condensers used in these tests were made with waxed paper, a method discarded by us several years ago as quite useless for practical engineering work.—Yours, etc.,

Swinburne and Co., Limited.

Teddington, December 13, 1893.

LIGHTNING EXPRESS SERVICE.

Sir,—I notice in your issue of the 8th instant a small paragraph headed "Lightning Expresses Unbearable," in which you say that it seems another point adverse to my proposal that the physical strain upon drivers and stokers of high-speed trains in the United States is very considerable. Allow me to observe that the natural conclusion to be drawn from this phenomenon appears to me exactly the opposite. If the strain had been so severe on the *passengers* as to tell on *their* health there might be something in the argument, but it is the peculiar nature of the work to be performed by an engine driver travelling on a locomotive at such a high speed which creates the objectional results you mention; and as in my proposed lightning express service there are no engine drivers or stokers, the only objectionable class of work is eliminated, and it renders the service quite possible without injury to the health of the officials of the train. The electrician who works the train instead of the engine-driver will have no harder work at the speed of 150 miles than at 30 miles an hour, and will not be exposed to any of the influences which certainly must render the occupation of an engine-driver under such circumstances absolutely unbearable.—Yours, etc.

T. Behr.

10, Drapers'-gardens, E.C., December 12, 1893.

[We presume that Mr. Behr has someone to take charge of his express service—call him by what name he pleases, and the responsibility involved by 150 miles per hour will not fail to have its effect on nervous systems. We again reiterate our statement that Mr. Behr's plan is neither desirable nor practicable. It will be sufficient for us to prove our thesis when he asks for public money. Up to that point he can argue as much and as long as he likes.

We do not suppose any person ever pays attention to the flapping of the wings of our bantam contemporary, that seems to imagine snarling is sense; choleraic writing, knowledge; and whose office is like that of the stage puppet, to dance to those who pull the strings. We might suggest that too much of silly inanities is calculated to madden all concerned therein.—Ed. *E. E.*]

LIEGE-HERSTAL TRAMWAY.

Sir,—We noticed the account which appeared in your paper dated December 1st, 1893, concerning the Liège-Herstal electric tramway, and read same with great interest. May we take the liberty of bringing to your notice that not all the statements contained therein are quite correct. In particular we beg to point out to you that the two dynamos—each of same is giving 100 amperes at 550 volts at a speed of 700 revolutions—are not made, as you say, by the Allgemeine Elektricitäts Gesellschaft, of Berlin, but by our company. We may say that the former firm has not taken any part whatever in this undertaking and in the supply of any machinery for same.

The fact is that our firm, on taking the entire temporary responsibility for the perfect working of the Liège Herstal electric tramway, concluded the contract with the Société des Tramways Liègeois. We calculated the project, executed it, and put up the whole plant, having constructed ourselves in our works at Liège all the electrical machinery included therein. You would oblige us, therefore, by making a statement to this effect in one of your next numbers.

We profit of this occasion to draw your attention to another very important electrical plant put up by our firm—we mean the transmission of power and electric lighting installation in the Fabrique Nationale d'armes de guerre at Herstal. The electromotive power for the

working of all the machines and machine tools, as well as the lighting by electricity of the whole establishment, is obtained there by our multipolar dynamo—type H. Pieper—of 500 h.p., coupled direct to a Corliss compound engine of the same force.

Beginning of this year the plant has been enlarged by another of our dynamos—type H. Pieper—of 300 h.p., coupled direct to a Willans of the same power.—Yours, etc.,

COMPAGNIE INTERNATIONALE D'ELECTRICITE
(H. Pieper, jun., Director).

Liège, December 12, 1893.

CROMPTON-BRUNTON ALTERNATOR.

Although Messrs. Crompton and Co.'s name has hitherto been chiefly known in connection with the supply of

Fig. 1.

direct-current machinery, they have always had a full appreciation of the advantages of the high-pressure alternate-current system for all work where the distribution has to be carried out over widely-

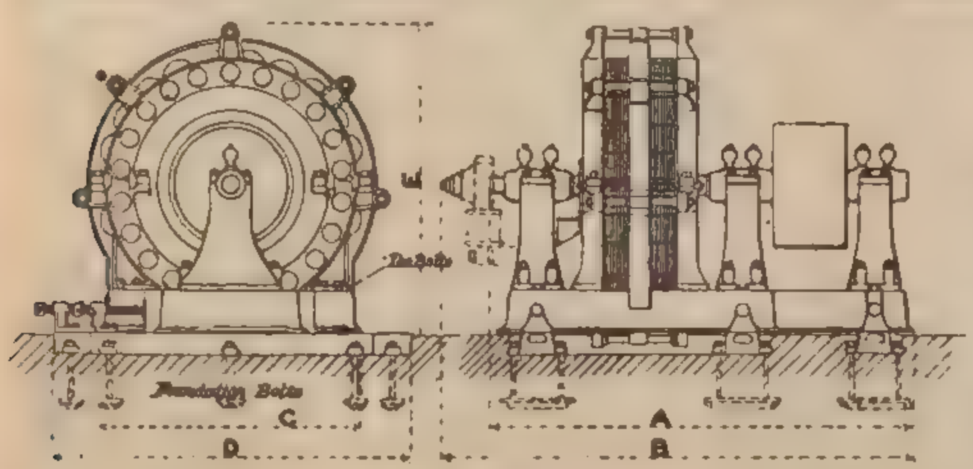

Fig. 2.

scattered districts where the lamp density is too low to pay for the larger amount of copper required for a direct system, and they have in carrying out many of their contracts, where the conditions warranted it, made use of the alternate-current system. They have for some time past occupied themselves in working out a complete system of alternate current machinery, and they believe that they have, while proceeding on well-tried lines, by a careful attention to proportions and mechanical details succeeded in turning out designs which will in practice prove thoroughly reliable and extremely efficient. The most important item of such a system is of course the alternator, and we illustrate below a 60-kilowatt machine, Fig. 1. These alternators have revolving armatures and stationary field magnets. This choice has only been made after careful consideration and considerable experience with both types. Special attention has been paid in this machine to the following points: (1) a ready access to the armature, for inspection or repair, by opening one or both upper halves of the field magnets which are hinged for that purpose; (2) facilities for easily removing and securely replacing armature coils; (3) the provision of a powerful magnetic field and small armature reaction, so that the alternators shall require but little variation of exciting current to suit variation of load; (4) high efficiency, both at full and light loads. The high efficiency has been obtained by the provision of an armature without any iron core, also by the reduction of the power required for the excitation of the field to a minimum, and also by the use of a light revolving armature giving a minimum of weight and loss of power at the bearings, and, as a consequence—not the least importance—a minimum of trouble. The armature is of the well-known disc pattern formed of sector-shaped coils fixed round a periphery of the hub. Probably the parent design of this type of armature is that described in Siemens's original specification of 1878; such an armature is, electrically, probably the best that could be devised, and it is only in the constructional details and proportions that improvements are to be looked for. The special features of the armature as constructed by Messrs. Crompton and Co. are the methods adopted for attaching each armature coil to the centre disc, or hub, and the provision made for drawing it radially inwards toward the centre, so that the whole armature when mounted can be very securely tightened up, thus entirely preventing all detrimental vibration of the armature conductor, and making a very strong and rigid job. Moreover, a new armature coil can be quickly inserted at any time and tightly drawn into place. The field magnets, bearings, and other portions of the machine are of the usual type, and call for no description. The collector is entirely enclosed, to prevent all risk from accidental contact, and the brushes are in duplicate, so arranged that either may be removed for inspection when the machine is at work. The machine illustrated is designed to work at an E.M.F. of 2,000 volts at 600 revolutions, and it has been in almost daily use for the past eight months. It has been frequently run for experimental purposes (with increased speed and excitation) at over 3,500 volts. The power required for the excitation of the field at full load is only 1½ per cent. (750 watts), and the commercial efficiency exceeds 91 per cent. Messrs. Crompton and Co.'s standard sizes of these alternators range from 15 kilowatts to 200 kilowatts, those from 65 kilowatts upwards being provided with three bearings, as shown in Fig. 2.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE VI

(Continued from page 5[illegible].)

Formula for Flow of Gas in Pipes.—Let P_1 P_2 be the initial and terminal pressures in a main of length L (foot units). The velocity of flow is given by the equation†:

$$u_1 = \sqrt{\left\{\frac{g\,c\,T\,m}{\zeta\,L}\;\frac{P_1^2 - P_2^2}{P_1^2}\right\}}$$

where u_1 is the velocity at the inlet of the pipe. For pipes of circular section and diameter d, $m = d/4$. For lighting gas, $c = 130$; for Dowson gas, $c = 64$. Let the temperature be 60deg. F., or the absolute temperature T = 521deg. Then c T = 67,730 for lighting gas, and = 33,344 for Dowson gas. ζ, the coefficient of friction, = 0·005. Introducing the numerical quantities:

For lighting gas—

$$u_1 = \sqrt{\left\{181{,}700{,}000\,\frac{d}{L}\,\frac{p_1^2 - p_2^2}{p_1^2}\right\}}$$

For Dowson gas—

$$u_1 = \sqrt{\left\{89{,}450{,}000\,\frac{d}{L}\,\frac{p_1^2 - p_2^2}{p_1^2}\right\}},$$

where the pressures are in pounds per square inch. When the initial velocity of flow is given, and the terminal pressure is required in terms of the initial pressure:

For lighting gas—

$$p_2 = p_1\sqrt{\left\{1 - \frac{u_1^2\,L}{181{,}700{,}000\,d}\right\}}.$$

For Dowson gas—

$$p_2 = p_1\sqrt{\left\{1 - \frac{u_1^2\,L}{89{,}450{,}000\,d}\right\}}.$$

Case I.—In an ordinary gas distribution the difference of pressure producing flow is small, being about 2½in. of water. If p_2 = 14·7lb. per square inch, p_1 = 14·7361, and

$$\frac{p_1^2 - p_2^2}{p_1^2} = 0·00506,$$

the equations reduce to

$$u_1 = 959·4\sqrt{\frac{d}{L}}\text{ for lighting gas,}$$

$$= 673·2\sqrt{\frac{d}{L}}\text{ for Dowson gas.}$$

The quantity of gas delivered in cubic feet per hour will be $3{,}600 \times \frac{\pi}{4}\,d^2\,u_1$. Assume a distribution to a distance of 5,000ft. Then with the given pressure difference of 2½in. of water column, the quantities of gas discharged and its equivalent in power will be as follows:

A.—LIGHTING GAS.

Diameter of main in inches.	Initial velocity in main. Feet per second.	Cubic feet of gas delivered per hour.	H.P. at 26·5 cubic feet per h.p. hour.
6	9·59	6,782	256
12	13·57	38,350	1,447
24	19·19	217,100	8,189
36	23·50	598,000	[illegible]
	B.—DOWSON GAS.		
6	6·73	4,758	53*
12	9·52	26,910	299*
24	13·46	152,300	1,692*
36	16·48	419,600	4,662*

* Horse-power at 90 cubic feet per horse-power hour.

It will be seen that none of the velocities under this pressure are excessive. The Dowson gas being heavier, the friction is greater and the quantity flowing is less. Farther, as the heat value of Dowson gas is less than that of lighting gas, the amount of power transmitted in a main of given size is only about one-fifth as much for Dowson gas as for lighting gas.

Case II.—It may next be enquired what would be the result of using greater pressure to force the gas through the mains than is usual in supply for lighting. In ordinary gas mains it is found inadvisable to increase pressure because of the increase of leakage. In the distribution of gas for power purposes, this objection would have less weight. The network of mains would be simpler, and the consumers being fewer, there would be fewer joints and valves to cause leakage. By the adoption of some really efficient joint like that used in the Paris air mains, leakage could be almost reduced to zero. The pressure which would then seem to be desirable for a gas power distribution is the pressure which would produce in the mains the highest desirable velocity of flow. It may be taken from the analogy of compressed air mains that 45ft. per second is a quite unobjectionable velocity. Assuming this velocity as the initial velocity in the mains, the problem is to find the necessary initial pressure. The equations become—

$$p_1 = \frac{p_2}{\sqrt{\left\{1 - \frac{L}{89{,}730\,d}\right\}}}$$

for lighting gas, and

$$p_1 = \frac{p_2}{\sqrt{\left\{1 - \frac{L}{44{,}180\,d}\right\}}}$$

for Dowson gas.

For a transmission to a distance of 5,000ft. we get the following results:

A.—LIGHTING GAS.

Diameter of main in inches.	Initial velocity. Feet per second.	Initial absolute pressure lbs. per sq. inch.	Difference of pressure producing flow. Inches of water.	Quantity of gas. Cubic feet per hour.	H.P. transmitted.
6	45	15·59	24·6	31,800	1,200
12		15·12	14·4	127,500	4,199
24		14·0	5·5	509,000	19,210
36	–	14·84	3·9	1,145,000	43,200
		B.—DOWSON GAS.			
6	45	16·70	55·4	31,800	353
12	—	15·64	26·0	127,000	1,413
24	–	15·15	12·4	509,000	5,655
36	—	15·09	8·3	1,145,000	12,722

ELECTRICAL TRANSMISSION OF POWER.

In 1877, Dr. William Siemens indicated the practicability and the probable commercial importance of the electrical transmission of power to considerable distances. In an address to the Iron and Steel Institute he stated that a copper rod 3in. in diameter would transmit 1,000 h.p. a distance of 30 miles. Later, in 1883, he delivered a lecture at the Institution of Civil Engineers on the electrical transmission and storage of power. But he was able to describe as practically working transmissions little else than the Lichterfelde and Portrush railways. Deprez had at that time experimentally transmitted 3 h.p. 25 miles, through ordinary telegraph wires at 2,000 volts, obtaining a return of 32 per cent. only of the energy expended.

It has from that time been hoped that one of the largest fields for electrical enterprise would be, to use the title of Sir W. Siemens's lecture, the transmission and storage of power. Countless predictions have been made in electrical journals that some advance in invention had been accomplished which would revolutionise the conditions of the use of motive power. In these lectures it is necessary to keep to the stable ground of achieved results, and, regarding these alone, the conclusion is unavoidable that the amount of electrical distribution of power actually in operation up to the present time is really comparatively small. Two years ago, Mr. Kapp gave some interesting lectures on the electric transmission of power. In those lectures he describes only a single case of electrical transmission of any magnitude which was then in operation. That was the installation at Schaffhausen, where about 500 h.p. was being electrically transmitted across the river. Since then the striking Frankfort-Lauffen experiment has been carried out, and power transmitted successfully, and without more than about 25 per cent. loss, a distance of 108 miles. High-tension continuous currents from dynamos in series have been used in two or three cases for transmissions to distances up to 28 kilometres. The synchronous alternating method is in operation at Telluride, Colorado, but over a short distance, and in favourable circumstances; but when all such cases have been taken into the reckoning the aggregate power at present transmitted electrically is not very great.

No doubt electrical transmission of power to great distances is possible by more than one method. It is a condition in such a case that a very high tension, 20,000 to 40,000 volts or more, should be used, or the cost is excessive. That such currents will be used seems likely, but can hardly yet be reckoned as accomplished, at least on a large scale, and with commercial success.

In a great deal that has been said about the electrical distribution of power one thing has been forgotten. It is that there have always been means of transmitting power to considerable distances, and if such transmissions are rare, it is not because they would fail mechanically, but because the cost of transmission is too great for profitable application of the power. Motive power was transmitted four miles by compressed air in 1861, before electric transmission was thought of. If electrical transmission is to play an important part it will only be when it can be carried out so cheaply that the power can be supplied to consumers at a cheaper rate than they can manufacture it for themselves.

In the distribution of electrical energy from central stations for lighting purposes a great deal has already been accomplished. Financially, electric lighting operations appears also to be

* Howard Lectures delivered before the Society of Arts.

† Unwin. "Distribution of Power by Compressed Air." *Proceedings*, Institution Civil Engineers, vol. cv.

succeeding, though it is too early to estimate the measure of their success. But a higher price will be paid for energy for lighting than for energy required for power. In towns like Geneva, where electricity can be generated by cheap water power, and where gas costs 7s. per 1,000 cubic feet, the success of electric lighting is assured. In other cases the great convenience of the electric light will no doubt counterbalance some excess of cost when compared with other means of lighting.

In one other case, which is strictly a case of power distribution from a central station, electrical engineers have achieved a remarkable success. In the United States there are now some 4,000 or 5,000 miles of electric tramways, which are working with complete mechanical success. It does not appear that the cost of electric traction is much lower than the cost of horse traction. For one of the oldest and best managed tramways, the West End Street Railway of Boston, the working cost of traction has been given at 22 cents per car mile for electrical traction, and 24 cents per car mile for horse traction, the earnings per car mile being about the same in both cases. But the electric cars attain speeds of 10 to 15 miles an hour, and in American towns, with wide spreading suburbs, they have great advantages. Almost with no exception—probably the Budapest tramways are the only important exception—the electric tramways which are in successful operation have cheap overhead conductors carried on posts. Such a system is not suitable for European towns, and with more expensive methods of carrying the conductors the success of electrical traction is at least more doubtful.

A case where electricity is likely to be used very successfully in transmitting motive power is in working traffic on underground and overhead railways. When passenger trains have to be run at short intervals on a line with numerous stations, electric motors distributed over many carriage axles have great advantages, besides freedom from smoke and steam. It is possible that, even in working cost, the electric motor will be superior to the steam locomotive. But this, again, is a case where cost of power is not a governing consideration, or where, at least, a considerable price can be paid for power.

For both lighting purposes and traction purposes a high price can be paid for power. But when power is distributed for industrial purposes, the question of cost is much more important, and the progress of electrical methods of distribution has been much less rapid. Every electric lighting company would be glad to supply power, if only to increase the day load and so to reduce the idle time of the machines, and in a very few cases power is taken from electric lighting mains. Mr. Shoolbred has stated that in Bradford a few electric motors for hoists, lathes, and other purposes have been fixed. But at 6d. a unit the cost per effective horse power is £60 per annum (3,000 hours). At that rate the power can hardly be used except for occasionally-worked or intermittent machines. Even if electricity were sold for power purposes at half the price charged for lighting the cost of the power would be greater than that of steam or gas power.

(*To be continued.*)

THE FUTURE OF ELECTRIC RAILWAYS.

A lecture was delivered on Monday before a crowded audience, in the Chemical Theatre of the Owens College, by Dr. Edward Hopkinson on the subject of electric railways.

Dr. Hopkinson, after a reference to the extent to which electricity is now used for traction purposes, directed attention to the essential features common to all electrical tramways or railways, illustrating his remarks by some interesting experiments with a number of working models. With regard to the electric railway running underground in London, Dr. Hopkinson stated that since the opening of the line the locomotives had run 1,300,000 miles, and a traffic of 18,000,000 passengers had been provided for. Already five schemes had been authorised by Parliament for similar railways in London alone, and Paris, Brussels, Vienna, and Berlin were considering similar undertakings. Concerning the best means of producing the electrical power, he had to say that here, at any rate, in England this, as for electric lighting, was dependent upon the economical production of steam power; but there were essential points of difference between the conditions under which steam power was required for electric traction purposes and for electric lighting. In Scotland and Ireland, however, and many countries abroad, particularly in Switzerland and Italy, there was abundant water power, now only very partially utilised, which might be easily rendered available for working electric railways. Some instructive details were then given of the comparative cost of electric and steam power. The City and South London line had, he said, enabled experiments to be made on the efficiency of the railway system as a whole, taking into account the loss of power in the generators, on the line, and in the motors, and in the resistances of the locomotives. The loss in the line was about 11 per cent. of the electrical power generated, and the efficiency of the locomotives as a whole was 70 per cent.; thus the electrical efficiency of the entire system was 62 per cent. The trains weighed, with full load of 100 passengers, about 40 tons, and the average speed between stations was 13.5 miles per hour. The cost of working, including all charges, during the last half year was 6½d. per train mile. It was perhaps hardly a fair comparison to compare the cost of working such a line as the South London line with the cost of steam traction on other lines, inasmuch as steam could not possibly be used in the tunnels, only 10ft. 6in. diameter, in which this line was constructed, but the comparison was not uninstructive. Take the Mersey Railway, where the gradients and nature of the traffic were similar. On the Mersey Railway the locomotives weighed about 70 tons, and the train, which was capable of carrying about 350 passengers, 150 tons. According to the published returns of the company, the cost of locomotive power is 14d. per train mile—i.e., more than double the cost on the South London line, but for a train weighing between four and five times as much, but capable of carrying only three and a half times the number of passengers; thus the cost of steam traction per ton mile of train was about half that per ton mile of train for electric traction. But it was not on the cost per ton mile that the success of a passenger line depended. The real basis of comparison was the cost per passenger mile, and here electric traction had great advantage over steam, as the dead-weight of the electric motor was small compared with the dead weight of steam locomotives of the same power; and with electric motors the trains could be split up into smaller units at but slightly increased cost, so permitting a more frequent service. We could not expect, therefore, that electric traction, with our present knowledge, would take the place of steam traction on our trunk lines; but it had its proper function in the working of the underground lines now projected for London, Paris, Berlin, Brussels, and other large towns, and also, he thought, on other urban lines; for example, on the Liverpool Overhead Railway, where trains of large carrying capacity were not required but a frequent service was essential; and finally, also, on those short lines, whether independent or branches of the great trunk lines, where water power was available. When he undertook the construction of the Bessbrook line it was a condition that the cost of working should be less than the cost of working by steam, a condition which the first six months of working showed to be successfully fulfilled. When Messrs. Mather and Platt undertook the construction of the electric plant for the City and South London Railway they guaranteed that the cost of traction for a service of 8,247 miles per week, as actually run, should not exceed 8½d. per train mile. Their anticipations had been more than realised, the actual cost being now 6½d. per train mile only. There were, however, other projects, both in America and on the Continent, for electric railways on which the special feature was to be an enormously high speed of travel, speeds of 150 and even 200 miles per hour being promised. With a steam locomotive, involving the reciprocating motion of the piston and connecting rod, such speeds were probably unattainable, but they might be realised in the purely rotary motion of an electric motor. But at such high speeds as these, the power required to overcome the air resistance was of special consideration. Assuming, however, that the ordinary laws of air resistance hold good, he calculated that the power required to propel an ordinary train 200ft. long at 200 miles per hour against the resistance of air alone, apart from the frictional resistances, would not be less than 1,700 h.p. Though there was nothing to prevent the construction of electric locomotives capable of developing this, or even greater power, the strength of the materials at present at command would set a limit to the speeds which may be obtained. If, however, modern civilisation required a speed of travel of over 200 miles per hour, he ventured to predict that it would be more efficiently realised by regarding it as a problem in projectiles and not of ordinary locomotion. In conclusion, Dr. Hopkinson pointed out how Joule's researches had prepared the way for the great developments of electrical engineering at the present day. Thus they realised, said he, why it should be, and why, as he believed, it was, that here in Manchester Joule was honoured, and his name and work familiar to not only men of science, but to every intelligent employer, every foreman or draughtsman—nay, every 'prentice boy engaged in the vast circle of engineering industries of which Manchester was the centre.—*Manchester Guardian.*

LEGAL INTELLIGENCE.

STRICK v. LATIMER CLARK, MUIRHEAD, AND CO., LIMITED.

This case was heard before Mr. Justice Wills on Tuesday in the Queen's Bench Division. It was a claim for commission.

Mr. J. W. McCarthy appeared for the plaintiff, and Mr. Lockwood, Q.C., and Mr. Pollard for the defendants.

According to the plaintiff's case, the defendants requested him in 1889 to introduce them to certain persons who were about to acquire parliamentary powers for establishing a system of electric lighting in certain areas of the city of Westminster and the defendants promised the plaintiff that if he obtained for them the introduction, and if, in consequence, the defendants secured a contract

or did business with the persons mentioned, the defendants would pay the plaintiff a commission. In February or March, 1889, the plaintiff introduced the defendants to Mr Browne Martin, the chairman of the Westminster Electric Supply Corporation, and that introduction resulted in a contract on December 5, 1889, by which the corporation agreed to do certain works for not less than £100,000. The plaintiff claimed £1,000 commission. The defendants denied there was an introduction by the plaintiff, and further, that if any commission was due the amount claimed was excessive, as the contract of December 5 was not definite, and in fact, an action had been brought on it, and after being heard for two days before Mr. Justice Hawkins and a special jury in May, 1891, a settlement had been arrived at by which the defendants accepted £4,000 in satisfaction of all claims and costs. The defendants further contended that they had always been ready to give some gratuity to the plaintiff for obtaining the signature of Mr Browne Martin to a document, and they paid £40 into court in satisfaction of all claims.

Evidence was given on both sides, and much correspondence between the parties read.

Mr Justice Wills, in giving judgment, said that in cases of this kind, where there was a conflict of testimony about conversations, there could be no better way of getting at what actually took place than by looking at the correspondence. Here the plaintiff had claimed commission from the first. It was remarkable that if the Board, composed of the defendants, had always taken the view that no commission was due, and £40 was to be the only remuneration, nothing appeared to that effect on the correspondence. He thought the plaintiff was entitled to a commission as the introducer of a gentleman with whom the defendants afterwards did business. The only question was how much. It was understood that the amount was to depend on the business ultimately obtained. There was no principle on which the amount of commission in this case could be calculated, but, having regard to the settlement of the action before Mr. Justice Hawkins for £4,000, he thought £300 would be a proper amount to allow the plaintiff.

Judgment was given for the plaintiff for £260 beyond the £40 paid into court.

COMPANIES' MEETINGS.

GENERAL ELECTRIC POWER AND TRACTION COMPANY, LIMITED.

Directors: The Earl of Albemarle, K.C.M.G., A.D.C. (chairman), Lord Egerton of Tatton, Moritz Immisch, Esq., Sir Henry C. Mance, C.I.E., Thomas Parker, Esq., M.Inst.C.E., James Pender, Esq., J.P.

Report of the Directors submitted to the shareholders at the third ordinary general meeting held at Winchester House, E.C., on December 12, 1893.

The Directors beg to submit the balance sheet and profit and loss account for the year ended 30th September, 1893. At the last annual meeting the shareholders were informed that arrangements had been made with the Electric Construction Company, Limited, by which that company undertook the management of the affairs of this Company. The Directors have pleasure in stating that this arrangement has worked very satisfactorily, and the following comparative figures indicate the economies which have been effected in the management. The trading accounts for the past year show a profit on the manufacturing department of £1,010. 12s., and a profit on launch department of £31. 14s. 2d., whereas for the previous year the accounts showed losses of £3,121. 14s. 2d., and £570. 10s. 3d. respectively. Furthermore, the expenses of management, exclusive of Directors' fees have been reduced from £3,727. 15s. 5d. in 1892, to £556. 17s. 2d. in the past year. The Directors have decided to cancel the amount of £862. 10s. standing to their credit at the end of September, 1892, and have debited the past year with only £186. 18s. in respect of remuneration. During the past year the Directors have determined sundry unprofitable transactions by sales and closing of leases, and have made provision for possible depreciation on such of the dismantled plant as is still unsold. The accounts, however, do not deal with the larger question, raised by the auditors in their report of January last, whether the book value of patents and goodwill should be further reduced. The Directors regard it desirable that the capital should be brought into conformity with the real position of affairs, and they are giving this matter their further consideration with a view to a reorganisation of the Company. The question of removing the manufacturing works referred to in the last report has received the anxious consideration of the Directors, and, with the assistance of the new management, they hope to overcome this difficulty in a way which offers many advantages over the original plan of removing the works to Millwall. An agreement has been made, subject to the approval of the shareholders, for an amalgamation with the Acme Electric Works at Kentish Town. This arrangement has the merit of providing suitable manufacturing works already equipped at a smaller annual cost for rent and other standing charges than that at present incurred by the Company, and avoids the heavy cost of removing machinery to a distance, and the serious disorganisation of the current business which this would involve. The copper depositing works at Millwall are now completed, and the question of providing the necessary capital for commencing operations is receiving the consideration of the Directors. In accordance with the articles of association, Mr. *Moritz Immisch and* Mr. James Pender retire by rotation, and offer themselves for re-election. The auditors, Messrs. Ward and Wilding, also retire, and offer themselves for re-election.

The third general meeting of this Company was held on Tuesday at Winchestor House, E.C., to receive the report of the Directors and the balance sheet as given in the preceding column, and to consider and, if deemed advisable, to pass the following resolution

"That this meeting approves the agreement submitted to it, made between this Company and a trustee for the Acme and Immisch Electric Works Limited, relating to the sale to the latter company of the Kentish Town branch of this Company's business, and authorises the Directors to carry the same into effect subject to such modifications, if any, as they may determine."

Lord Egerton of Tatton presided, and in moving the adoption of the report and accounts, said that they were drawn up in such a way that the shareholders could clearly see the position of the Company. He was sorry that the general depression of trade still affected the Company, and that in the four branches, which in the first instance there was a good prospect of developing, they had not succeeded as they thought they would do. In the case of electric traction, in consequence of the North Metropolitan Tramways Company not taking up the experiment which they had successfully instituted at Barking, and as the success which they had been able to show there had not been sufficient to induce municipal corporations to undertake electric traction, they had been unable to carry on that work. They would see from the balance sheet that there was a depreciation on account of the Barking plant, which they were now endeavouring to dispose of, and which was at present unprofitable. With regard to launches, there had been a slight profit, but not such as to induce them to go on and increase that branch very largely. There did not seem to be any large demand for that class of business, and he thought it would be wise if they could profitably dispose of that plant, and be able to concentrate their operations on the manufacturing business and upon the copper depositing branch There was a loss on the general balance sheet, but, on the other hand they had very much diminished the expenses of management, which had been undertaken by the Electric Construction Company, who, as preference shareholders were largely interested in the Company. They had struck off £802 as Directors fees and the latter for the present year had been reduced to the very lowest amount. With regard to the manufacturing works, it was necessary to leave, owing to the termination of the lease. There was an idea, mentioned in the last report, of transferring the Kentish Town works to Millwall, but that would have been a very costly removal. The Directors had therefore decided to recommend to the shareholders an amalgamation with the Acme Works, whose establishment was in close proximity and was well equipped with suitable machinery for the manufacture of electrical apparatus, and the plant would be transferred there The Directors considered it desirable that this amalgamation should have effect by the formation of a new company, to be called the Acme and Immisch Electric Works, and it was proposed that the new works should be managed as the Company was now namely, by the Electric Construction Company in order to save the expense of a separate staff, and by that means a great deal of the subsidiary work that the Electric Construction Company now performed could be carried out, and the works be fully employed at a very much less cost than if a separate management existed. The terms of the amalgamation were based upon the relative value of the two works, in which the Company would receive five eighths and the Acme Company three eighths of the capital. It was proposed that the capital should be £25,000 of which £20,000 would be in fully paid ordinary shares in the proportion mentioned and it would require £5,000 in preference shares as working capital. The copper depositing works at Millwall had been finished but the state of the copper trade, which was in a very different position to what it was when the works were commenced, had rendered it a question as to how far it would be profitable to start them at the present time They were waiting for a favourable opportunity, and were considering the matter of providing the necessary capital for beginning operations as soon as the market was in a favourable condition for them to do so With regard to the general position of the Company, it was quite evident that under present circumstances the capital of the Company was not fully represented by its assets, and that there was a debit balance against it of £76,000. It was quite clear that some reorganisation of the Company would have to be undertaken. At present the preference shareholders would have the first claim upon any profits made upon the present capital The present was certainly not a favourable time for starting any new commercial transactions, and therefore, although the general policy of the Board had been to endeavour to reduce the expenses and to try to dispose under as favourable circumstances as possible of the existing works which they had which had in previous times been a source of loss, they were sensible that a general scheme of reconstruction must before long be carried, and they were giving the matter serious consideration When a proposal was ready, they would call the shareholders together and submit it to them.

Mr Moritz Immisch seconded the motion for the adoption of the report and accounts.

A **Shareholder** enquired about the manufacturing department, and upon what the profits were made. It seemed to him that they were very much at the end of their tether.

Another **Shareholder**, who complained of the bad management of the launches on the Thames, asked whether it was not possible to arrange for the launches not to be taken further away than the storage permitted? The launches had a bad name on the Thames, and had sometimes to be towed back.

Mr. E. Garcke, in explaining the position of the Company, said that the Electric Construction Company simply took up the position of managers of this Company The result of that had been a decided economy in expenses His time had been largely engaged in liquidating and closing up transactions which in the opinion of the Board it was undesirable to carry on. With regard to manufacturing operations, at the time the Company was formed it took over the business of Immisch and Co., who made motors and other electrical apparatus. That business had not been quite as satisfactory as it was, and it had been their desire to work it up again, and this amalgamation would have the effect of reviving the former credit of Immisch and Co. as makers of motors, dynamos, and other apparatus. That profit which was shown in the first portion of statement No 1. had been made entirely on manufacturing and contracting. There had been a loss in that department in previous years, but this year it was on the right side With regard to the position of the ordinary shareholders in respect to the proposed amalgamation, the proposition was to form a new company, and to transfer the manufacturing business of the General Electric Power Company to that company, receiving in consideration fully paid up shares in the new company. It was the new company which would issue preference shares, and the shareholders in this company would be in the same position as before. Until some reorganisation or reconstruction of the Company was carried out, the position of the shareholders would undergo no change. The formation of the new company would have the advantage that, whereas at present the manufacturing works of the General Electric Power Company could not be carried on by reason of the lease expiring, by the amalgamation they would be able to obtain suitable works and machinery without any outlay of capital He admitted in a large measure the justice of the remarks concerning the bad management in the past of the electric launches They had, however, done better on the Thames this year, and in order to put that department on a satisfactory footing some new arrangement would be necessary.

The motion for the adoption of the report and accounts was then put and carried unanimously

The retiring directors were then re-elected and the auditors were reappointed

The **Chairman** then put the resolution proposing the amalgamation, and after some discussion it was adopted.

HOVE ELECTRIC LIGHTING COMPANY.

The first annual general meeting of this Company took place at Hove on Tuesday. The chairman, Colonel A. J. Filgate, R.E., presided The Directors' report was given in our last issue.

The **Chairman**, in proposing the adoption of the report and balance sheet, pointed out that up to September 30 the Company had issued 3,290 shares, producing £16,450; that on that date they were in debt to their bankers to the extent of £2,500 on account of a loan guaranteed by the Directors, and that their other liabilities amounted to over £8,500, the bulk of which was due to the contractors Against those liabilities they had the value of the actual work executed in the temporary and permanent generating stations, mains, plant, etc., £24,761, cost of meters, £583; office furniture, £69, and outlay on preliminary expenses and installation suspense account, £908 The revenue account up to September 30 showed a debit balance of £264 10s., and considering the small demand during the early months of the Company's operations that must be deemed satisfactory On July 1 they had 52 houses connected with the system, representing 3,778 33-watt lamps; at the end of September the houses supplied had increased to 72, and the 33-watt lamps to 5,478, and at the present date they had 86 houses and were supplying the equivalent of 6,225 33-watt lamps. Agreements had been signed for 14 additional houses which would shortly be connected with their system, and from enquiries they had received they believed that number would soon be considerably increased They understood that the Hove Commissioners were about to extend the light to the Town Hall, and they hoped the lighting of some portions of the town with arc lamps would soon be put in hand On the whole, there was every probability of the demand for the current being largely increased at an early date Owing to the comparatively small amount of capital they had been able to raise up to the present time, the Directors had not

had an easy time, but they trusted the shareholders would be satisfied with what they had done and the position which the enterprise had attained. But for the action of the contractors in carrying out the work of their contract largely in excess of the amounts for which the Company were able to pay, they could not have attained that position. The capital needed for the construction of the first portion of the mains and the temporary generating station was, as they were aware, found by the Directors and their friends, and no appeal was made to the public for subscriptions until after the supply of electricity was commenced. He was sorry to say the appeal then made did not produce the amount of capital they anticipated, nor did a second appeal made in the spring of the year. Being, however, fully satisfied with the progress made in the demand for electricity in Hove, and believing in the ultimate financial success of the undertaking, the Directors and Messrs. Crompton and Co. determined to do all in their power to push on with the work and fulfil the contract with the Commissioners. A main item in the contract was the erection of a permanent generating station, and as the demand for electricity was steadily increasing, it became apparent that in addition to the contract obligation of the Company, the increased power provided by the permanent plant would soon be needed to meet the requirements of the public. Under these circumstances, the Directors obtained a temporary loan of £5,000 on their personal security, to be devoted to the construction of the permanent generating station and electrical works, and the result was that those works were now approaching completion and would, they hoped, soon be brought into use. In the meantime, the demand for the electric current had so rapidly increased, while the days were also becoming shorter, that they were obliged to increase the temporary plant to ensure the demand being satisfied. The work the Company was doing in supplying electricity was largely in excess of what it was ever anticipated the temporary plant would be called upon to perform. Over six miles of mains had been laid, and more would have been put down but for a difficulty experienced in getting a sufficient supply of the Crompton Davis castings, which had to be used in the places where, owing to the position of the cellars, they were unable to construct concrete culverts. Their general policy in constructing mains was to tap the streets most likely to yield customers for the current—a policy which had been approved by the Commissioners, and one which they intended to adhere to as far as possible. From an approximate account of the working of the Company each week since July 1, he said that while in the earlier weeks the accounts showed a loss, that loss gradually diminished until near the end of September when the returns commenced to show a profit, which had steadily increased since, and he thought it might be safely anticipated that the accounts for the half-year ending December 31 would show some profit after meeting all administration and other charges. This was a result which must be considered as highly satisfactory for the second half year in the life of a new enterprise, working under considerable difficulties and with temporary machinery and plant. Having devoted a considerable amount of time to looking into the affairs of the Company, he believed it was likely to prove a financial success. Their progress was distinctly more rapid than he had anticipated, and everything pointed to its continuing. Their undertaking was a local one, and so far as he could gather their reputation was good, and it was generally believed that the Company would be a remunerative investment. Notwithstanding these favourable circumstances, their appeals to the public of Hove had not met with the response they hoped to obtain, but he was fully aware that the present year had been about the worst on record for investments, and that the public were very much averse to putting their money into anything but what were called "gilt-edged" securities. They had no hesitation in recommending their enterprise to the people of Hove, and hoped they would soon supply the necessary capital to complete it. He had been informed some misunderstanding existed as to the probability of their Company yielding good dividends, based apparently on the stipulations contained in the provisional order of the Board of Trade of 1890, that any excess of revenue after meeting certain charges and paying 5 per cent. on the capital invested in the electrical works should be utilised in reducing the authorised charges for electricity. But in the deed transferring this order to their Company, which deed had been approved by the Board of Trade, it was specially provided that the clause of the provisional order was not applicable to the Company. Further, it was provided that no charge could be required from the Company in their schedule of charges during the first seven years of their existence. After that period the Hove Commissioners could only move the Board of Trade to reduce their scale of charges if the Company, in the seven years preceding, should have earned such a profit as would enable them to pay dividends at the rate of 10 per cent. per annum for the whole of such period. The Chairman concluded by expressing the satisfaction of the Directors with the excellent way in which the works had been carried out by Messrs. Crompton and Co. and their staff; their thanks to their own staff, and to the Hove Commissioners and their staff for the assistance they had always afforded, and especially to the chairman of the Commissioners, Mr. Woodruff, for the cordial support he had given the undertaking and the interest he had taken in it.

Mr. Carleton E. Tufnell, who seconded the adoption of the report and balance-sheet, was supported by **Mr. R. E. Crompton**, who joined in the appeal of the chairman to the inhabitants to make the undertaking a local one. They wanted local support, and the money paid by the users of the light to be a source of income to the residents of Hove themselves. Speaking of the *generating* plant, Mr. Crompton said the design was the latest, *and would work most* economically. The works' cost had been reduced to a certain figure per unit, 3·3 lower than had ever been accomplished before for the same outlay. The more widely the remarkable results of the enterprise so far were ventilated the better for the Company, which wished to increase their capital to complete their works, and for the users of the light, because cheap manufacture meant cheap prices eventually.

On the motion being put, it was unanimously adopted.

BUSINESS NOTES.

Birmingham.—The electric light has been introduced in the Art Gallery.

Lanner.—The lighting of Lanner is occupying the attention several of the leading parishioners.

Western and Brazilian Telegraph Company.—The receipts for the week ended December 8 were £3,453.

Twickenham.—It has been decided for the present not to proceed further with the proposed electric light scheme.

Globe Telegraph and Trust.—The directors have declared an interim dividend of 1s. 3d. per share, payable on the 18th prox.

Liverpool Overhead Railway Company.—The traffic receipts of this railway for the week ending 10th inst. amounted to £686.

Canterbury.—The name of Alderman Mount has been added to the members of the Electric Lighting Committee of the Town Council.

Newport (Mon.).—The tenders for the electric lighting plant for the municipal station will probably be given out on the 21st inst.

West India and Panama Telegraph Company.—The receipts for the two weeks ended November 30 were £2 less than for the corresponding period.

Ulverston.—The Health Committee of the Local Board have passed a plan of a new boiler house and electric lighting house for Messrs. Pollitt and Co.

Porthcawl.—The Local Board have decided to accept the tender of the Porthcawl Electric Company to erect 23 lights and maintain them at £2. 10s. per annum.

Swansea.—A Swansea councillor is reported to have a scheme in his mind for lighting Swansea Docks and Harbour by means of a dynamo and a waterwheel.

Penistone.—The clerk stated at a meeting of the Local Board that he had written to the Sheffield Electric Lighting Company for certain particulars, but they were referred to the Brush Electric Company.

Gilsland Spa Company.—This Company has been registered with a capital of £15,000 in £10 shares to adopt a certain agreement, and to carry on the business of hotelkeepers and suppliers of gas and electricity.

Aberdare.—The Local Board have received an application from Messrs. Gery and Rhys asking the Board to assent to the lighting of the town by electricity. The question is to be discussed at the first meeting in January.

Incandescent Lamps Wanted.—Mr. E. C. Trevor Roper, of Okehampton, has written to a provincial contemporary asking where incandescent lamps can be obtained at 1s. 6d. each, "probably only serviceable for 100 hours."

The Charge of Forgery.—Mr. Henry Everard Hunt, manager of the Taunton Electric Light Works, has been committed for trial on charges of forging and uttering two promissory notes for £233 and £44, with intent to defraud.

Eastern Extension Company.—The Eastern Extension, Australasia, and China Telegraph Company, Limited, have declared an interim dividend for the quarter ended September 30 of 2s. 6d. per share, tax free, payable on January 16.

Belfast.—Queen's Quay is now lighted by the electric light. At a social gathering in connection with the fire brigade last week, it was mentioned that Mr. J. H. Greenhill had carried out the electric lighting of the fire brigade buildings.

Leamington.—The sub-committee appointed to consider the advisability of lighting the parish church by electricity has submitted a report recommending that an installation should be put down, at a cost not exceeding £280. This report has been adopted.

Blackburn.—In proposing the adoption of the minutes of the Gas Committee of the Town Council, Alderman W. Thompson withdrew all the clauses relating to the question of electric lighting, for the further consideration of which he proposed to again call the committee together.

Taunton.—The Town Council on Tuesday adopted a report of the Electric Lighting Committee recommending that the various courts in the town should be lighted by incandescent lamps, and that the town be lit by electricity until dawn, instead of leaving the streets in darkness at 3 a.m.

Islington.—The Vestry have adopted a resolution instructing the Electric Lighting Committee to consider whether any part of the works in connection with the generating station in Eden-grove can be satisfactorily carried out by the Vestry itself, without the intervention of a contractor.

Lynton.—The Lighting Committee of the Local Board having reported on the advisability of having an ornamental iron pillar at the cost of about £20, on which to put an arc light, the committee have been requested to reconsider the matter, as in the opinion of the Board the work could be done equally well at a less cost.

Rotherham.—The town clerk announces that the borough of Rotherham require a teacher to conduct a class in theoretical and practical chemistry, two nights per week, at the School of Science and Art, Rotherham. Applications to be sent to Mr. H. H. Hickmott, town clerk, Council Hall, Rotherham, not later than the 18th inst.

Halifax.—A special meeting of the Council is to be held to consider a recommendation of the Gasworks and Electric Lighting Committee that the proposed central electric lighting station should be erected on land belonging to the Corporation situated on the south side of King street, and not on the gasworks land, as previously selected.

National Telephone Company, Limited.—The directors of this Company have declared interim dividends for the half year ending October 31, 1893, as follows. On first and second preference shares at the rate of 6 per cent. per annum, less income tax; on third preference and ordinary shares at the rate of 5 per cent. per annum, less income tax.

Commercial Cable.—The Commercial Cable Company has determined to redeem on the 15th January next the whole of the outstanding mortgage debentures of the Company, being 800 debentures of £100 each, and notifies that the principal sums will be payable at the offices, 12, Queen Anne's gate, S.W., of Messrs. Siemens Bros. and Co., Limited.

Folkestone.—The Town Council have received a letter from the Borough Association stating that the members desired to strengthen the hands of the Corporation, in order that they might retain the power of providing electric light for themselves, and not part with it to a private company. The report of the Electric Light Committee is not yet ready.

Dudley.—Alderman Bagott mentioned at a meeting of the Town Council that it was desirable to show the Council and the town that the Streets and Gas Committee were looking after their interests in the matter of the electric light. It was, however, not desirable that they should spend some thousands of pounds for an order, and then not be able to go on with it.

Venezuela Telephone and Electrical Appliance Company, Limited. Messrs. E. D. Oppert and Co. have this week offered for sale £50,000 of 5 per cent. first mortgage debentures of £100 each at the price of £87½ per cent., repayable at par on October 1, 1910, or at the Company's option any time after July 1, 1895, at £105, upon six months' notice of redemption.

Coventry.—The Town Council have passed the minutes of the General Works Committee referring to a letter of objection addressed by the town clerk to the Board of Trade with respect to the proposed transfer of the undertaking of the Coventry and District Tramways Company to the Coventry Electric Tramways, Limited, and to correspondence thereon between the town clerk, the Board of Trade, and Mr. Graff Baker.

Electric Drilling and Riveting Machines.—The Thames Ironworks and Shipbuilding Company have acquired the sole right of manufacture for the United Kingdom of Mr. F. J. Rowan's electric magnetic drilling, riveting, and caulking machines, which have already met with much favour among shipbuilders and bridge builders. In portability and convenience of handling these machines are claimed to be much superior to hydraulic tools.

Partnership.—As will be seen from our advertisement columns, an old established firm of manufacturing electrical engineers is desirous of arranging for the admission to partnership of an electrician, or a pupil who has just finished his apprenticeship. He will be required to take control of special branch, and introduce £2,500 for the extension of it. Applications to be sent by letter to "Chartered Accountant," care of Bates, Hendy, and Co., 37, Walbrook, E.C.

Monmouth.—Mr. Edwards asked, at a meeting of the Town Council last week, whether steam or gas would be used as the motive power for the new system of drainage. The Mayor calculated they would not want to put down motive power for 12 months after the granting of the loan. By that time he hoped to have a provisional order for the electric lighting. The Town Council on Tuesday approved a memorial to the Board of Trade asking for a provisional order for lighting the borough by electricity.

Tenders for Harrogate.—It will be seen from our advertisement columns that the Corporation of Harrogate invite tenders for concentric insulated cables for high-pressure distribution. Specifications may be obtained on application to Mr. Samuel Stead, borough surveyor, Municipal Offices, Harrogate on payment of £1. 1s., which sum will be returned on receipt of a *bonâ fide* tender. Sealed tenders, endorsed "Cables," must be addressed to the chairman of the Electric Lighting Committee, and are to be sent in to the town clerk's office by the 30th inst.

City and South London Railway.—The employés of Mr. John Talbot, contractor, who have been engaged on the recently completed extension contract at Stockwell terminus for this Company, through the combined generosity of Mr. Talbot and the Company, have been entertained at dinner at the White Bear Tavern, Kennington Park road. The receipts of the Company for the week ending December 10 were £911, against £933 for the same period last year, or a decrease of £22. The total receipts for the second half year of 1893 show an increase of £158 over those for the corresponding period of 1892.

Electric Construction Company, Limited.—At a meeting of this Company, held at the offices, Queen street chambers, Queen street, E.C., last week the resolutions passed on the 16th ult., altering the articles of association, were confirmed. The directors notify that, in accordance with the deed of trust dated August 16, 1893, various numbers of debentures to the amount of £2,060, for payment at par on January 1 next were on the 8th inst. publicly drawn at the offices of the Electric and General Investment Company, Limited (the trustees), in the presence of Mr. C. J. Watts, notary public.

Swan United Electric Light Company.—The accounts of this Company for the year ending September 30, 1893, have been before the directors, and, subject to audit, they have resolved to recommend the shareholders to declare a dividend as follows: 3s. 6d. per share on the 78,949 ordinary shares of the Company, £3 10s. paid, and 4s. 3d. per share on the 19,750 £5 fully paid shares, free of income tax. This, together with the interim dividend paid on June 20 last, will make a total distribution of 7½ per cent. for the year on the ordinary £3 10s. paid shares of the Company. The warrants will be issued on the 23rd inst.

Aberystwyth.—On the recommendation of the Main Roads Committee, the Cardiganshire County Council agreed on Tuesday to allow the Bourne and Grant Electricity Supply Company to lay their electric light mains along the main road from Capel Bangor to Aberystwyth, subject to the work being done as directed by the county surveyor, and to the deposit by the company of the sum of £50 with the county treasurer to cover any cost the county may incur in restoring the surface of the road and making good any damage done in the carrying out of the works, and subject also to an annual payment of 5s. for the easement.

Newcastle.—The City Lighting Committee have arranged, with regard to the electric lamps at the top of Grey street, that a survey should be made of the same at the beginning of the new year, with a view to effecting still further improvements in that particular part of the city. An order has been given for a lamp to be erected in Raby street, Byker. The new hall which has been erected in Northumberland road, and to which the name "Olympia" has been given is lighted by means of hundreds of electric lamps and gas lights. The electric light fittings, etc., have been supplied by Messrs. Parsons and Co.

Dover Electricity Supply Company.—The subscription list of this Company, which is being formed with a capital of £50,000, closes to-morrow. The capital is made up of 10,000 shares of £5 each. The sum of 10s. per share is payable on application, 10s. on allotment, and the remaining £4 will be called up as required, in sums of not more than £1 per share at intervals of not less than two months. Prospectuses and forms of application for shares can be obtained at the bankers, the National Provincial Bank of England, Dover and London, and at the offices of the Company, 49, Queen Victoria street, London, E.C.

Abergavenny.—When the Improvement Commissioners discussed the question of gas lighting last week, Mr. Jenkins said that one thing which had struck him was the number of places where they were going in for the electric light, and as long as the Gas Committee was not able to do anything until next spring, it was a matter which he thought they ought to give attention to, and make enquiries in that direction. Personally, he was opposed to the electric light, but they could not shut their eyes to the fact that in many places they were putting in large and costly installations. The committee should make some enquiries on the matter.

Burton-on-Trent.—The Town Council have adopted the report of the Gas and Electric Light Committee which contained several recommendations for increased lighting accommodation, chiefly in Horninglow and Winshill. Various works, estimated to cost £100, were stated to be necessary at the electric light depot, and permission for their execution was granted. In moving the adoption of the report, Alderman Lowe said that the electric light works were making good progress, and that Mr. Ramsden, the gas manager, hoped to have the new illuminant ready for the use of the public by the end of January. So far, they had not received a great number of applications.

Bootle.—When the minutes of the proceedings of the Finance Committee of the Town Council were moved on Wednesday, Councillor Quayle asked if something could not be done about lighting the Town Hall with electricity. When there was a bazaar, a concert, or public meeting in the hall they found that the ventilation was not so good as was desirable, and he thought that with the new light, which would not cost very much, a great improvement would be noticeable. Councillor Swyny said that the subject of electric lighting was under the consideration of the committee, and no doubt he would be able to give the Council more information upon it at a future date.

Portsmouth.—The Town Council have referred to a committee a resolution that the Town Hall clock tower should be illuminated nightly within one hour of sunrise. The clock is wired for electric lighting. The Electric Lighting Committee at a meeting a few days ago, submitted certificates from Messrs. Waller and Manville for payment to the contractor for buildings of £300; to the contractors for boilers, engines and electrical plant, £4,000; and to the contractors for conduits etc., £2,000. The amounts were ordered to be paid by the Council. A sum of £500 was also ordered to be paid to the engineers (Messrs. Garnett, Waller, and Manville), on further account of their commission, making with previous payments of £200 and £300, two thirds of the commission agreed to be paid.

Lighting in Westminster.—The Highways Committee of the London County Council reported on Tuesday that they had considered two notices from the Westminster Electric Supply Corporation of intention to lay mains in various streets. The committee recommended that the sanction of the Council be given to the works referred to on condition that the company give two days' notice to the Council's engineer before commencing the work; that the mains be laid under the footways wherever it is found prac-

ticable to do; that before any street boxes are constructed the designs for, and the proposed positions of, them shall be submitted to and approved by the Council's engineer, and that the covers thereof shall consist of iron frames filled in with materials to suit the paving.

St. James's and Pall Mall Company.—Lords Justices Lindley, Smith, and Davey, sitting in the Court of Appeal, last week heard the appeal of the St. James's and Pall Mall Electric Light Company, Limited, against the decision of Mr. Justice Kekewich, who held that the plaintiffs in the action of Fry and Francis v. the St. James's and Pall Mall Electric Light Company, Limited, were entitled as holders of founders' shares in the Company, to have paid to them one half of two sums of £1,000 set aside by the directors as a redemption fund. Their Lordships held that half of the profits above a specified amount went to the holders of the founders' shares, and the £2,000 set apart was included in "profits" to which they were entitled. The appeal was dismissed, with costs.

London County Council Inspector.—The Highways Committee of the London County Council reported on Tuesday that the Council on November 3, 1891, appointed Mr. A. E. Rossiter, on probation for 12 months, at a salary of £200 a year to discharge the duties of an inspector under the Electric Lighting Acts. When the time came for the confirmation of the appointment, the committee were not in a position to judge fully Mr. Rossiter's qualifications for the post, and on their recommendation the Council, on November 15, 1892, extended the period of probation for another year. The committee have now satisfied themselves of Mr. Rossiter's ability to discharge the duties devolving upon him, and recommended that the appointment of Mr. A. E. Rossiter should be confirmed.

The Ealing Tenders.—The following is a list of the tenders received by the Ealing Local Board for the building of the engine and boiler house, etc., at the central station:

Wilkinson Bros., Finsbury Park (accepted)	£7,381	0	0
H. Vernon, Dewey lane, Derby	7,610	6	10
J. Dorey and Co., Brentford	7,900	0	0
J. Allen and Sons, Palmerston Works, Kilburn, N.	8,426	13	0
W. H. Lorden and Son, 107, Trinity road, Upper Tooting	8,461	0	0
S. and W. Patterson, 5, Whitehall, London, S.W.	8,584	0	0
J. Mowlem and Co., Grosvenor Wharf, Westminster	8,662	0	0
W. Gibbin and Son, 21 to 24, Pickering place, Bayswater	9,780	0	1½

Electric Lighting at Bristol.—The Town Council on Tuesday discussed the subject of electric lighting. It was announced that in the cost of building the central lighting station alone, the original estimate had been exceeded by no less than £19,000, chiefly owing to the heavy cost of piling the foundations. A local paper states that it had always been understood both by the Electric Lighting Committee and the public generally, that if at any future time it was desired to extend the light farther than the present experimental area, all that would be necessary would be to lay new mains in the districts proposed to be so lighted. It was, however, mentioned at the meeting that if they desired to extend the light, not only would new mains have to be laid, but the whole of the mains already laid would have to be taken up and relaid.

Grimsby.—A meeting of the Public Lighting Committee of the Corporation has been held to consider the provisional order for electric lighting, a copy of which had been supplied to each member. In reply to a question the Town Clerk said the period in which the works were to be carried out was two years although they had hoped for three years. This was, however, the usual order made by the Board of Trade, but they could get the time extended if necessary. Mr. Connell moved, and Mr. Grainger seconded, that the Council be recommended to approve the order. The Mayor expressed the hope that if they found the electric light would be an advantage, before the expiration of two years they would be supplying it to the town. He remarked that many large shopkeepers had expressed a wish to have the light. The resolution was adopted unanimously.

Richmond Sewerage Works.—The contract for the lighting of the Richmond main sewerage works, Mortlake, which was entrusted to Messrs. Drake and Gorham, has now been completed, and the trial run of 12 hours of the whole plant with all the lights on proved very successful. There are 56 8 c.p., 16 c.p. and 32 c.p. lamps for general purposes, four 300 c.p. lamps for lighting the engine room, and a 400 c.p. lamp has been fixed for the outside tanks. As a considerable amount of moisture is always present in the well and mixing room special precautions have been taken to prevent any possible leakage. A supper was given on the 4th inst. on the formal taking over of the installation when testimony was borne as to the amicable understanding existing among all concerned during the carrying out of the work. Mr. A. H. Preece was retained as consulting engineer and Mr. Fairley, the engineer to the Board, supervised the work generally.

Bradford.—A scheme is on foot for the introduction of electric cooking ovens into Bradford, and a sample oven has been sent by a Birmingham firm of makers to Mr. Baynes the manager of the Corporation Electricity Works, for exhibition. Mr. Baynes has handed the oven over to Mr. J. Bentley, of the Bradford Coffee Tavern Company, who is making arrangements for a thorough test of the apparatus at the Exchange Café, Market street. The oven is of the Crompton type. Alderman Moulson (chairman of the Gas and Electricity Supply Committee), in moving on Tuesday the adoption of the minutes of the committee, said that he and the deputy chairman had been to Huddersfield to visit the gas and electricity works in that town. The electricity works were on a larger scale than those at Bradford, and had been built upon a site better suited for such a purpose than the land possessed by the Bradford Corporation at Bolton road. The Huddersfield works were capable of being extended as found desirable.

Lighting of Harrogate.—A Local Government enquiry is to be held for obtaining sanction to loans for the various works to be undertaken by the Corporation, including sewage disposal, baths extension, street improvement, electric lighting, etc. The engineer's plan for the suggested modification of the compulsory electric lighting area has been approved, and the town clerk has been instructed to forward the same to the Board of Trade, and ask for approval. It has been resolved that the buildings and plant for the electric light shall be erected on a site on the Corporation farm, near the Skipton road. The electrical engineer (Mr. Wilkinson) has been instructed to complete his detailed report on the installation. At a recent meeting, Mr. Meyer moved an amendment that the question of the destructor be not entertained. The Mayor seconded and contended that it would be folly to add a refuse destructor to the electric lighting plant, as they would be adding extra cost to a scheme which he was afraid would be a burden. Mr. Ward contended the scheme would be of great advantage to the town, and he was supported by Mr. Simpson. It was decided by 12 votes to 4 to adopt a refuse destructor, and also that the site should be on the side of the farm near Skipton road.

The Newport (Mon.) Tenders.—The following is a list of the tenders received for the erection of the buildings and foundations for the machinery for the municipal electricity works of the Corporation:

W. Gradwell, Cardiff, and Barrow-in-Furness (accepted)	£4,750	0	0
J. H. Firbank, Newport	5,080	0	0
T. Evans, Cardiff	5,243	10	6
A. S. Morgan and Co., Newport	5,250	0	0
W. Lissaman, Limited, Mickleton	5,320	0	0
W. Price, Newport	5,334	0	0
J. Francis and Son, Newport	5,380	0	0
A. E. and J. D. Parfitt, Newport	5,455	0	0
H. C. Parfitt, Newport	5,500	0	0
G. Geen, Newport	5,618	0	0
C. H. Reed, Newport	5,984	0	0
Paragon Patent Roofing Company, Smethwick, glazing only	92	0	0

No less than 52 separate tenders for the supply of electric plant had been received, and these have been referred to Mr. Hammond for his examination and comparison.

Glasgow.—The Lord Provost, in a review of the past year's work of the Corporation, mentioned last week that the third branch of work that the Watching and Lighting Committee had in hand was the lighting of the city. Here the feature of the year had been the introduction of electricity as a street illuminant. Since the current was switched on the main arteries of traffic in the central area of the city had been lighted by that agent, and now electric light pillars were being erected along the main thoroughfare of Argyll street and Trongate from the site of the old Gushet House, Anderston, to the Cross. With regard to the gas and electric lighting department, two important works had been completed during the year. The new electric light station in Waterloo street was opened on February 25 last. This station was designed for the supply of electricity within the central area of the city and the building and plant originally put down, including the street mains, had cost about £80,000. The plant at first put down was to supply about 12,000 lamps of 8 c.p., but so great had been the demand that as many as 15,000 lamps of 8 c.p. had been supplied, while the number of consumers was still increasing, and the committee had had to give authority to the electrical engineer to lay down additional distributing mains, engines, boilers, and dynamos.

Stafford.—An enquiry was held on Wednesday by Colonel W. M. Ducat, R.E., respecting the application of the Corporation to the Local Government Board to borrow £20,000 for the purpose of electric lighting, and £2,000 for the purpose of extending the accommodation of the public baths. The town clerk, Mr. M. F. Blakiston, explained that the Corporation obtained powers in 1890 to supply the electric light, but no further steps had been taken, as it was found that there was no immediate demand for the light. At the end, however, of 1892 the County Council applied to the Corporation for a supply of electric light to the new hall which they were erecting. This would give them a good customer for about 500 lights, and he had no doubt that others would soon follow when they could get started. An estimate for the cost of an installation for immediate requirements had been made by Mr. J. F. Bell, the gas engineer, and approved by Dr. Hopkinson, of London, at £12,000. It was, however, thought advisable, in view of the very probable extension which would be required, to provide for this, and they therefore asked for a loan of £20,000. Dr. Hopkinson thought that the extension indicated would be required during the first year. He felt confident that a profit could be made from the works. The inspector subsequently visited the site of the proposed electric light works.

Walsall.—The General Purposes Committee of the Town Council have recommended the adoption of a report of the Electric Lighting Sub-Committee, and application to the Board of Trade for their approval of the adoption of a system of electric lighting for the borough on the principle suggested in the report, viz., high tension, with transformers. They also recommended that application should be made to the Local Government Board for their sanction to a loan of £19,650, in addition to the suggested site at

the Wolverhampton street Gasworks, for the cost of carrying out the proposed scheme, and that contracts should be made as follows, as soon as the sanction and approval of the central authorities had been obtained viz., with the Electric Construction Company for the electrical plant, for £10,093; with Messrs. Bumsted and Chandler for the engines, for £1,350; and with Messrs. H and T Danks for the boilers, for £805. The Mayor, in explanation of the position of the Council in this matter, said if the Corporation did not at once do this work a private body could come in by the authority of the Legislature and undertake it. The committee had given the most careful attention to the question of electric lighting, and he was satisfied that the installation they proposed was not going to do much injury to the gas undertaking. The report has been adopted.

Lighting at Bolton. The Gas and Electricity Committee of the Corporation have fixed Wednesday next for the ceremony of laying the corner-stone of the electricity buildings on Spa road, Alderman Miles, J.P., having been requested to officiate. The tenders for the work are considerably below the original estimate of £18,132 for the scheme at present in contemplation, but the addition of another engine and alternator will bring the cost up £21 295, and this plant, it is expected, will be adequate to supply the borough with electricity for some years. The excavating and foundation laying has been well advanced, and during the progress of this work a spring of water has been discovered which will prove of much value to the department, it being intended to use this water for supplying the boilers. The dimensions of the engine room and boiler house are 83ft. 6in. by 46ft., and the total frontage of the offices is 80ft. The building work is being pushed on as speedily as possible under the supervision of Messrs. Hinnell and Murphy, architects, and the putting down of plant and laying of mains, which will be done under the direct personal superintendence of Mr. J. H. Rider, M.I.E.E., electrical engineer to the Corporation, will be commenced forthwith. As some misunderstanding exists locally as to the nature of the charges to be made for the supply of electricity, a table has been drawn up by the engineer to make this matter clear.

Traction at Cork. At a meeting last week of the Standing Committee of the Corporation a letter was read from Messrs. J. W. Bourke and W. B. Ronan. The writers stated that they "send you the resolution of the Corporation as to the use of electricity, which the directors wish to have altered as we have amended same, making the working of the tramcars by electricity or horse power optional as desired by the promoters. Please get amendments passed at the next meeting of the Standing Committee, and confirmed at the meeting of the Council on Friday next." Alderman Crean said that they objected before, and they would object again, to having overhead wires through the city. Mr. Gutman said the overhead wires were already passed. The Chairman said that it was found impracticable to work the underground wires. The overhead wires would be placed 24ft. from the ground, which would ensure safety. Alderman Crean said that overhead wires were not allowed in any city in the kingdom, and he did not see why they should be allowed there. The Chairman said that several cities had been mentioned to them in which overhead wires were allowed. Mr. Rahilly said that he did not see why there could be any objection to that portion of the scheme. Alderman Hungerford proposed that the amendment be made. Mr. Rahilly seconded the proposition, and it was passed.

Plymouth. At a meeting of the Town Council on Monday, Mr. Jinkin moved, and Mr. Kerswell seconded, a resolution approving of the resolution passed some little time since sanctioning an application to the Board of Trade for a provisional order authorising the Council to supply electricity for public and private purposes within the borough. Mr. Pethick suggested whether some amicable arrangement could not be made with the gas company, who were also seeking parliamentary power for electric lighting. Mr. Bond pointed out that the gas company had long had notice of the intention of the Council, and as the matter concerned a monopoly in which the convenience, comfort, and lighting of the town were involved, he hoped the Council would go on with their own proposal, irrespective of any other. Mr. Harvey asked if the adoption of the resolution would commit the Council to a large expenditure. In the tramways they had quite sufficient unremunerative enterprise. The Town Clerk said the resolution was necessary if the Council wished to have powers to supply the electric light. The cost of an unopposed electric lighting order was about £160. The gas company's Bill was brought forward after the Council had given notice of its intention to apply for electric lighting power, and it seemed to be promoted with the object of securing for the gas company a monopoly of the supply of light to the town. Replying to Mr. Pethick, the Town Clerk said if the gas company opposed the application of the Council for an electric lighting order they would not succeed in their opposition. On a poll being taken 30 members voted for the resolution, and none against, the remainder abstaining.

Lighting at Wolverhampton. A report has been presented to the Town Council by the Lighting Committee with regard to the scheme for supplying the electric light to the town. Originally a tender by the Electrical Construction Corporation to lay down the plant for a sum of £25 772 10s. was submitted for approval, but since the appointment of Mr. F. H. Lewis as electrical engineer to the Corporation, the scheme has been revised with a view to subdividing the contract. It is now proposed to provide a generating station in Commercial road, from which the electrical energy will be transmitted to a central station at the Town Hall. From this central station the high pressure current will pass to various substations in the compulsory area, which will be at the Art Gallery, Free Library, and Town Hall, where it will be transformed into low-pressure energy for distribution. The total amount of the new tenders, plus £1 320 estimated for arc lamps, is £18,762 14s. 2d., as against £25,772 in the original estimate. Other items of necessary expenditure will reach £4,020, and the total amount of capital expenditure for which a loan is sought will be as follows: Plant, £17,442 14s.; arc lamps, etc., £1 320; other capital items, £4,020; cost of buildings and contingencies, £7,228 5s.; total £30,011. The Mayor, in moving the adoption of the report on Monday, said with regard to the estimated cost of buildings and contingencies, that the plans had been issued, and the tenders would shortly be laid before the Council. The Lighting Committee were anxious to push the scheme on and to obtain the approval of the Board of Trade and the Local Government Board; but before this could be secured certain figures would have to be forwarded to the central authorities, in order that an inspector might be appointed to make enquiry into the matter. It was intended to apply for power to borrow £30,000 to carry out the scheme, but it was not intended to expend the amount at once. Alderman W. H. Jones seconded the motion, which was agreed to.

Electric Lighting at Chatsworth. A complete system of electric lighting has been carried out at Chatsworth House, the Derbyshire residence of the Duke and Duchess of Devonshire. All the rooms in the mansion that are being used have been fitted with the electric light in place of candles, which have hitherto been used. There are installed 850 incandescent lamps, ranging in candle power from 6 to 50. Between 40 and 50 men have been constantly employed on the work, which has been carried out in the absence of the Duke and Duchess, and when all the power is turned on the mansion is a blaze of light, which is rendered soft and subdued by means of tinted shades and various newly designed patents. This installation is of interest as showing the extent to which natural forces can be utilised for the generation of electricity. At a height of some 400ft. above Chatsworth House there exists a lake of some nine acres in extent, to which a pipe was laid some years ago for the purpose of supplying water to the well-known Emperor fountain. Mr. Drake, the electrical engineer, found that by tapping this pipe he could obtain as much as 150 h.p., or sufficient for all the lighting required. In the general arrangement of the lighting Mr. Drake's object has been to utilise all the handsome old fittings, for which purpose a special imitation electric candle has been introduced. This so nearly resembles wax in colour that it is impossible to distinguish the two when placed side by side. Where fittings have been added the style of each room has been carefully studied, and the fittings have been made to harmonise with the architectural requirements. In many of the rooms, such as the oakroom, where metal work would have been out of place, the lamps have been skilfully embedded in oak carving, worked on to the original panels, by which arrangement the lamps are almost invisible in the daytime. The installation has been designed and carried out by Mr. Bernard Drake, of Messrs. Drake and Gorham, 66, Victoria street, Westminster, with the assistance of the estate staff, working under the direction of Mr. Martin, the agent, and Mr. Woodhead, the clerk of the works.

Lighting of Camberwell. -The Vestry last week considered a proposal for applying for a provisional order. When the matter was brought forward, Mr. Phillips moved that the seal of the Vestry should be affixed to a memorial to the Board of Trade for a provisional order under the Electric Lighting Acts to supply electricity for public and private purposes in the parish. The speaker drew attention to Bradford, a town which more than any other could be likened unto Camberwell. In Bradford they supplied an area of 120 acres; in Camberwell they proposed to supply something less than 60 acres. In the former place they had 20 miles of mains, but they proposed to start with only 4½ miles of mains. Bradford supplied with electricity 26,263 lamps of 8 c.p., and in 12 months they produced 401,540 units. They charged 5d. per unit for lighting and 4½d. for motive power. The cost of production was 3·0910 pence, and they made a profit of £3,000 a year. In Bradford their capital was £48,880. In Huddersfield they sold electricity at 6d. per unit and it cost them 3d. per unit. After quoting statistics regarding other towns, he said he thought he had shown conclusively that what they required could be obtained for £50,000. He thought they could save a large amount upon the destruction of the last. He did not think, like Mr. Manville, that they could consume their dust without coal. He believed, however, they could dispose of at least 8,000 loads of dust at a saving of £1 000 a year. They were not asking that night to spend £50,000, it was only something like £100. They had already spent £100, and he felt sure that another £100 would enable them to secure the provisional order. Mr. Ben Ellis seconded the motion. Mr. Preston said that if they went into Mr. Philip's statement they would find that there was not the smallest comparison between the towns quoted and Camberwell. Bradford was a manufacturing town and Camberwell was a parish of paupers. He was perfectly willing to have the electric light, but at somebody else's expense, and not at the expense of the ratepayers. Northampton, a town of shoemakers, had been alluded to. There was no comparison in this case, for there he believed electricity was used more for manufacturing purposes than for lighting. All they would do in Camberwell by adopting electric lighting would be to drive a lot of people out of Camberwell because of the heavy rate. He moved the rejection of the motion, and Mr. Logg seconded. He thought they ought to study this dust-destructing business on its merits before they went in for this scheme. They also wanted one necessary thing, and that was the ability of the ratepayers to bear the extra burdens which the scheme might cast upon them. Mr. Perry hoped the Vestry would decide that night that, having spent £100, they had had enough of this business, and drop it. When a tradesman made a bad debt the best

thing to do was to write it off, and he thought they ought to do this with the £100 already spent. This was not an opportune time, and there was no analogy between Camberwell and Bradford. They had no manufactories, and Camberwell was a very straggling district. Mr. Finlay said, as the representative of a very poor district, he could not support this proposal. They should not go away with the idea that they were going to get off with £50,000. When that came to be paid for they would find it was £100,000. Mr. Harbord asked the supporters of this scheme if they were pursuing this policy because there was any demand for it from anybody. There seemed to be no one demanded it but Mr. Phillips, Mr. Parker, and a few others. He knew some electric lighting companies whose £5 shares were being offered at one-eighth of their value. Other companies were actually ashamed to show the figures. He did not think there was any hope that they would ever have a supply of electricity at a profit in Camberwell. Upon a show of hands the Chairman declared the motion rejected. A division was demanded and taken, with the result that the motion was not carried.

PROVISIONAL PATENTS, 1893.

DECEMBER 4.

23231. **Improvements in micro-telephones.** George Lee Anders and Walther Kottgen, 5, Great Tower street, London.

23241. **Improvements in electric storage batteries.** William Joseph Starkey Barber-Starkey, 70, Market-street, Manchester.

23253. **Improvements in electric alarms.** John Hutcheson Ballantyne, 115, St. Vincent street, Glasgow.

23283. **Improvements in couplings for connecting together conductors of electricity.** Leonard Penson, 433, Strand, London.

23303. **Improvements in or relating to accumulators.** Alfred Julius Boult, 323, High Holborn, London. (Jean Lecoq, Belgium.)

23304. **Improvements in or relating to arc lamps.** Alfred Julius Boult, 323, High Holborn, London. (Jean Lecoq, Belgium.)

23307. **An improvement in conductors and rubbers for electric railways or tramways.** Fritz Bernhard Behr, 28, Southampton buildings, Chancery lane, London.

23308. **Improvements in continuous-current dynamos, either for generating or for receiving electric currents.** Maurice Hutin and Maurice Leblanc, 28, Southampton-buildings, Chancery-lane, London.

23309. **Improvements in continuous-current dynamos, for either generating or receiving electrical energy.** Maurice Hutin and Maurice Leblanc, 28, Southampton-buildings, Chancery-lane, London.

DECEMBER 5.

23327. **Improvements in electric lamp fittings.** Arthur James Howes, 73, St. Stephen's road, Upton Park, London.

23331. **Improvements in electrical current regulators and electrical heating apparatus.** Samuel Wells Cuttris, The Elmwood Electrical Works, Camp-road, Leeds.

23337. **Improvements in electric motors.** Henry Capel Lofft Holden, Royal Arsenal, Woolwich, London.

[redacted] **Improvements in the manufacture or production of electrodes or plates for batteries, especially secondary batteries.** Herbert Green Spearing, 46, Lincoln's-Inn fields, London.

23366. **Improvements in phonographs.** Henri Jules Lioret, 52, Chancery lane, London.

23385. **A combined ammeter and voltmeter.** Edward W. Jewell and William Zimmerman, Norfolk House, Norfolk street, Strand, London.

23424. **Improvements in incandescent electric lamps.** Henry Green, 45, Southampton buildings, Chancery-lane, London. (Complete specification.)

23436. **Improvements in apparatus for electrolytically producing soda and chlorine.** Henry Harris Lake, 45, Southampton buildings, Chancery lane, London. (The Union Chemical Company, United States.) (Complete specification.)

DECEMBER 6.

[redacted] **The prevention of humming noise of dynamo-electric machines.** Frank Bailey, 17, South-street, Manchester-square, London.

23468. **A method of adapting incandescent electric lamps to table, standard, hanging, and other oil lamps.** Arthur Barton Kent, 47, Lansdowne-gardens, South Lambeth, London.

23472. **Improvements in electrical measuring instruments.** Francis Henry Nalder, Herbert Nalder, Charles William Scott Crawley, and Alfred Soames, 16, Red Lion-street, Clerkenwell, London.

23477. **Improvements in contacts for electrical signalling.** John Orme, 65, Barbican, London.

23478. **Improvements relating to the electrolytic preparation of oxygen and the halogens and to the simultaneous production of electrodes.** Alfred Coehn, 11, Southampton buildings, Chancery-lane, London.

DECEMBER 7.

23543. **Improvements in or connected with electric arc lamps.** Robert James Canavan, 27, Tavistock-place, Tavistock-square, London.

DECEMBER 8.

23,605. **Improvements in the method of attaching reflectors to electric lamp holders or sockets.** Percy Garnuss Ebbutt and John Benjamin Verity, Plume Works, Aston, Birmingham.

23614. **An improved instrument for controlling the flow of current through electric circuit or circuits.** Philip O'Neal, 191, Hampstead road, London.

23633. **An electric motor designed to drive continuously any clockwork or time-keeping mechanism.** James Parkin, 27, Sandhill, Newcastle on Tyne. (Complete specification.)

23669. **Improvements in electrolytic vessels for primary and secondary batteries or accumulators, and other processes of electrolytic decomposition and electrolytic action, such as for the extraction of metals from their ores, electro-depositions, and the like.** Paul Schoop, 28, Southampton-buildings, Chancery-lane, London.

23673. **Improvements in telephones.** Walker Moseley, 103, King's road, Peckham, London.

23676. **Improvements in and connected with primary batteries, and in safety lamps to be used therewith.** Howard Vivian Coad, 37, Cursitor street, Chancery-lane, London.

23684. **Improvements in connection with the electro-deposition of metals.** Thomas Bradford Bates and Arthur Ewbank Leefe, 55, Chancery lane, London.

23687. **Improvements in telegraphy and in the means employed for perforating tapes used for this purpose.** Patrick Bernard Delany, 24, Southampton-buildings, Chancery-lane, London.

23688. **Improvements in and relating to electric batteries.** Louis Fortoul and Charles Thorye, 45, Southampton-buildings, Chancery-lane, London.

DECEMBER 9.

23733. **Improvements in electrical means for signalling on railways in a fog and at other times.** Illius Augustus Timmis and George Neill Abernethy, 2, Great George street, Westminster, London.

23744. **Improved method of and appliances for lighting railway trains by electricity.** Ridley James Urquhart, 57, Barton arcade, Manchester. (Pascual de Ysasi Yasmendi, Spain.) (Complete specification.)

NOTES.

Leicester.—The Town Council propose to municipalise the tramways.

Rugby.—It is proposed to establish a telephone exchange at Rugby.

Threats by Telephone.—Threats are now being sent by telephone in Paris by anarchists.

Ayr.—Water power for electric lighting is under the consideration of the Town Commissioners.

Dublin.—It is proposed in March next to construct a double electric tramway between Blackrock and Dublin.

Light Railways. — The Shoreditch Vestry have suggested the construction of light (possibly electric) railways in the metropolis.

Smoking Concert.—The third grand smoking concert of Messrs. S. Z. de Ferranti, Limited, was held on Friday at the Blue Last Tavern, Ludgate-hill.

Geissler Tubes.—A paper on this subject was read a few days ago before the Yorkshire College Society of Chemists and Colourists by Mr. G. Hefford, B.Sc.

King's College School.—The Astronomer Royal, Mr. W. H. M. Christie, distributed, on Tuesday, the annual prizes, etc., gained by pupils at King's College School.

The Brighton-Rottingdean Railway.—The Bill for the laying down of this railway has passed through Parliament, and the necessary capital is said to have been privately subscribed.

The Blackpool Electric Tramway.—As will be seen from another column, Mr. T. Parker and Mr. Holroyd Smith are to overhaul this tramway and the plant, each on his own responsibility.

Royal Institution.—The members of this institution in special general meeting have recorded their deep regret at the death of Dr. John Tyndall, who was for 40 years connected with the institution.

Dowlais.—Differences have occurred between the local authority and the gas company. Feeling runs so high that Councillor Evan Lewis is reported to have declared that if an electric light company were formed, he would subscribe for a thousand pounds' worth of shares.

Civil Engineers.—The council of the Institution of Civil Engineers have recently nominated for election as honorary members the Duke of Devonshire, Dr. Edward Frankland, Captain Sir Douglas Galton, Prof. von Helmholtz, and the Marquis of Salisbury.

Developments in Telephony.—At the last weekly meeting of the Bradford Scientific Association a paper was read by Mr. E. E. Gregory on "Recent Developments in Telephony." The paper was amply illustrated by means of apparatus, diagrams, and lantern slides.

The "Medical Battery" Company, Limited.—Messrs. C. B. Harness, McCully, Hollier, and Towers were again brought up at Marlborough-street on Wednesday. Further evidence was given, and the case again adjourned. The charge against Mr. Towers has been withdrawn.

Faure's Accumulator Patent in Germany.—We understand that the Imperial Court of Appeal at Leipsic has just decided in an action brought by the Hagen Accumulator Company against certain manufacturers of secondary batteries in Germany that the employment of lead in the state of super-oxide, oxide, or insoluble salts as a filling material for accumulator plates comes under Faure's patent.

The Tickers are to Go.—It is understood that the committee of the Stock Exchange have resolved to adopt the views of the sub-committee to whom the question of the use of tape machines was referred for investigation. The sub-committee recommended that the machines giving Stock Exchange quotations should be directly under the control of the committee of the Stock Exchange. This decision is subject to confirmation at the next committee meeting, and if it is finally adopted its effect will be widespread.

Obituary.—We regret to announce the death of Mr. William Wallace Duncan, the well known stock and share broker and tramway expert. The deceased was the author of "Duncan's Tramway Manual," an excellent work on the financial position of English tramways.—The death of Henry Goebel, which has just taken place, removes from the world of electricity a rival of Edison's. Goebel maintained through thick and thin that he, and not Edison, was the real inventor of the incandescent electric lamp, and, as will be remembered, he did not hesitate to carry his case into a court of law.

Purification of Sewage.—M. Hermite, whose electrical process for the purification of sewage was referred to in our last issue, in connection with the experiments undertaken by the municipalities of Havre and Lorient in dealing with sewage by electrolysed sea-water, visited Worthing on Saturday to make arrangements for a series of experiments. M. Hermite was accompanied by Mr. Cooper, the electrical engineer who has been associated with M. Hermite in the work abroad. The spot selected as the scene of operations was West-street, close to the sea. The experiments will shortly be commenced.

Crystal Palace School of Engineering.—On Wednesday, Mr. A. R. Binnie, chief engineer to the London County Council, distributed the certificates gained by students of the school of engineering during the winter term. A series of reports by professional examiners showed that the work of the school has been conducted in a highly successful manner. In practical electricity Mr. George A. Goodwin, president of the Society of Engineers, considered that the knowledge of the students spoke highly for the style of instruction. Mr. Binnie afterwards addressed the students on the value and importance of engineering as a profession.

An Interesting Display.—Electric-avenue, which is situated quite close to Brixton Station, is this week illuminated by 60 Fyfe-Main arc lamps of 2,000 nominal candle-power, and by 1,200 fairy lamps interspersed amongst a hundred full-sized trees, and between the columns, the entire length of the colonnade, are suspended baskets of foliage lighted by incandescent lamps. In addition to these there is arranged across the road a large number of foliated festoons brilliantly lighted with electric lamps. The illuminations surpass in brilliancy and artistic effect those of last year, and which were generally admired and visited by thousands from all parts of London. The idea of illuminating and decorating Electric-avenue emanated from and was designed by Mr. A. L. Fyfe, of the Fyfe Main Electric Lighting Company.

Electricity in Mining. — The Aberdare-Merthyr Collieries Company, in the extensive colliery under their control, have introduced electricity in place of steam power for working the pumps underground. Before the members of the North Staffordshire Institute of Mining and Mechanical Engineers on Monday, Mr. R. H. Wynne read a paper on "The Application of Mechanical Arrangements in Underground Operations." With regard to motive power he classified the subject as follows: (1) horse-power; (2) steam;

(3) compressed air; (4) electricity; (5) combustion of petroleum. Mr Wynne pointed out the advantages and disadvantages of the different systems, showing that while each was valuable under certain circumstances, electricity, when further developed, would be sure to be extensively introduced for motive power as well as for lighting.

Lighting in Brazil.—A Devonshire paper mentions that two years ago Mr James T. Cornish was selected by Mr. W. H. Preece to go to Sao Carlos do Pinhal, Brazil, to erect works and instal the electric light. After many months of vexatious delays, caused by the Brazilian Customs authorities, he at last succeeded in transporting to the distant island city of Sao Carlos a complete lighting plant, with electric motors and equipment, so that now the station is supplying 2,000 lamps of 8 c.p. for private use, as well as over 200 street lamps. So successful has been the installation, and so satisfactory has the English-made plant proved in working, that several large towns in the neighbourhood have made overtures to Mr. Cornish, notwithstanding strenuous competition by German electricians, to instal the electric light in their respective municipalities.

Defective 'Bus-Lighting.—The London General Omnibus Company were summoned on Monday, at Bow-street, for failing to light five of their omnibuses. Mr. Hicks, who appeared on behalf of the company, reminded the magistrate that some similar summonses had been heard 10 days previously, and that he had then expressed the hope that there would be no recurrence of the offence. Unfortunately, the Bristol Electric Lamp Company, to whom the contract for lighting the omnibuses had been entrusted, did not appear able to carry it out effectively, and he was so dissatisfied that, at their next meeting, he intended to advise the Board to put an end to electric lighting and go back to oil lamps. A penalty of 3s. and costs on each summons was imposed. We might suggest that the London General Omnibus Company should experiment with electric lamps of some other company.

Sludge as Fuel.—Mr. G. F. Priestley, of Halifax, has written to the papers in reference to the Leeds sewage works at Knostrop, where thousands of tons of sludge are dried in the open air. He is convinced from the experiments tried lately that these heaps could all be burnt without smell, and that sufficient power could be derived therefrom (by the generation of steam) to drive all the pumping machinery at the Knostrop works; not only this, but to supply light to Leeds. At present the sludge is given to farmers, but it has been proved over and over again that it is worth next to nothing when lime has been used as a precipitant. When burnt in the new type of steam generators at Halifax (driving an electrical plant) it is worth, he remarks, about 4s. per ton for steam raising purposes, and can be made to burn with a bright quick flame. Mr. Priestley considers that the attention of sanitarians and electricians should be drawn to these facts.

Royal Meteorological Society.—The monthly meeting of this society was held on Wednesday, Dr. C. Theodore Williams, president, in the chair. Mr. C. Harding, F.R.Met.Soc., gave an account of the "Great Storm of November 16th to 20th, 1893." He stated that this storm was the most violent of recent years, and, so far as anemometrical records are concerned, the wind attained a greater velocity than has previously been recorded in the British Islands. The velocity of the wind was 96 miles in the hour from 8.30 to 9.30 p.m., November 16th, in the Orkneys, where the hurricane burst with such suddenness that it is described as like the shot of a gun; and the wind afterwards attained the very high rate of 90 miles and upwards in the hour for *five consecutive hours*. Many of the gusts were at the rate of 115 miles an hour, and at Fleetwood a squall occurred with the wind at the rate of 120 miles in the hour. The storm was felt over the entire area of the United Kingdom. The author had tracked the storm from the neighbourhood of the Bahamas on November 7, across the Atlantic, and over the British Islands to Central Europe on November 20.

The European Sims-Edison Electric Torpedo.—Captain Grice-Hutchinson, in the House of Commons on Monday, asked the Secretary of State for War whether he was aware that the European Sims-Edison Electrical Torpedo Company, having failed to obtain any assistance or encouragement from the officer deputed by the War Office to attend the trial at Stokes Bay in February, 1892, had in consequence to transfer its operations to France; whether he was aware that two of these torpedoes had been constructed by an eminent firm in France, and favourably reported on to the French Government by a committee of naval officers; and whether, in view of the fact that France might acquire the right to these torpedoes and the secret of their construction at any moment, he would give to the company such aid as might be requisite, so as to secure to this country the possession of what was one of the most advanced system of dirigible torpedoes at present known. In reply, Mr. Campbell-Bannerman said that the trials referred to had been kept under observation, and that it was not considered that the Sims-Edison electric torpedo had the advantages possessed by the torpedo already in the service.

Electricity in Warfare.—In the course of an article in a New York paper Lieut. Zalinski deals with the subject of the pneumatic gun he has devised, and which is to be charged with dynamite. Speaking of the fleet which has left New York for the use of the Brazilian navy, he says it is much more formidable than is generally imagined. He states that the "Nictheroy" is supplied with the Fiske electric range finder. This instrument gives the range with a very great degree of accuracy, the error being less than one-half of 1 per cent., as the instruments are mounted on the "Nictheroy." She has also other engines of modern warfare, which will now receive their first practical application. Some of the most important of them are the Howell torpedo, the Sims Edison dirigible torpedo, and the Halpin dirigible torpedo. The Halpin dirigible torpedo has been recently evolved, and the experiments made with it thus far indicate effective possibilities. Its motive power is said to be obtained from a storage battery carried within it, it being steered by wires by an operator on the boat or ship. It special advantage is that it is dirigible. It may be worked from a very small rowboat, or even by an operator swimming in the water.

The Central London Railway.—Sir Horace B. T. Farquhar, who presided on Tuesday at the annual general meeting of the shareholders of the Exploration Company, mentioned that the report was late in appearing, owing to its being expected that they would be able to announce the issue of the Central London Railway. Unfortunately, however, the state of finance generally in the City was such that it would have been impossible to make such an important issue. Great delay had also been caused from their having to submit all the plans of the proposed station close to the Bank of England for the approval of the Sewers Commissioners. This approval they only received last June, and between then and the present time it would have been impossible to have made such an important issue. The chairman said it was unnecessary to take powers for the extension of the time of the Act. The railway was a most important enterprise, and when completed would meet a great want of the people of London. The directors were quite confident that there would be an enormous traffic,

which was already waiting for it, and that it would also prove a highly profitable undertaking, as electricity, which would be the motive power, was cheaper than steam.

Telephony between Dublin and Belfast.—The work of erecting the trunk telephone line between Dublin and Belfast is making rapid progress, and already the section between the Irish capital and Drogheda is complete. It is expected that early in January the line will be ready for opening, and arrangements are being made at the general post offices at either end for affording the public facilities for carrying on verbal communications. It will be remembered that Belfast is already coupled up telephonically with Glasgow, the tariff for use of the line being 1s. per minute. This line being 150 miles in length, and the new line between Dublin and Belfast being about 105 miles, it is fair to assume that the tariff between the two latter cities cannot exceed the same amount. The conductor is solid copper wire, weighing 800lb. to the mile, and in the erection the spiral system is being adopted—that is, giving the wire a spiral direction from pole to pole—the object being to neutralise the effects of induction. By this arrangement the wire completes a spiral between every four poles. By way of comparison, it may be mentioned that the London-Paris trunk line is 300 miles long, and the tariff 8s. for the use of the line for a period of three minutes.

The City Telephone Tubes.—On Tuesday the clerk to the Commissioners of Sewers read a letter from the City of London Electric Lighting Company on the subject of the telephone tubes in the electric lighting conduits, and also a letter from the Exchange Telegraph Company asking that, in the event of permission being granted for the use of the pipes laid by the City of London Electric Lighting Company, the Exchange Company might be included in the licenses, so as to use the tubes for telegraphs and telephones. The City of London Electric Lighting Company, in their letter, asked that no further delay should take place in regard to the Commissioners giving their consent to the use of the tubes. With regard to the proposed charge of £8 per annum for telephones in the City, the company thought such a charge was not compatible with the outlay of capital, and pointed out, as stated in our last issue, that the reduction of charge to 3,000 telephone subscribers would mean that the proposed cheapening of the electric light to private consumers, who now numbered 25,000, could not be carried out. Mr. Gordon, in moving that these matters should be referred to the Streets Committee, remarked that there might be some modification in the terms made by the Commissioners, and that the charge for the telephone service should not exceed £10 per annum. Mr. Stapley seconded the proposition, and said he thought the present was a good opportunity for dealing with the company.

The Government and Telephony.—"There is still no sign," remarks the *Pall Mall Gazette* in yesterday's issue, "of the appearance of the Post Office contract with the National Telephone Company, which was promised to be exhibited to members in the autumn session. It is curious to note the difference in the attitude of the past and present Postmasters-General on this question. Sir James Fergusson, speaking in March last year, stated that, supposing local authorities were willing to take telephone contracts themselves, he did not see anything contrary to Government policy in such a proposal. A Treasury minute quoted by Sir James Fergusson on that occasion declared that the Government would comply with the reasonable demand of any town or district for telephonic facilities. Notwithstanding this very definite expression of opinion from his predecessor, Mr. Arnold Morley declines to act up to it, and in the case of Glasgow, for instance, has refused the facilities which Sir James Fergusson says the townspeople are perfectly justified in asking for. Attention will be drawn to this anomalous state of things in the House of Commons early next year by several members, among them Mr. A. C. Morton, who will set down a motion declaring that the Post Office telephone contract, and all that relates thereto, shall be referred to a select committee of the House, so that the local authorities of the United Kingdom shall have an opportunity of stating their views on the question."

Magnetic Rotation.—Mr. W. H. Perkin, F.R.S., is pursuing his experiments on the magnetic rotation of hydrogen chloride in different solvents, also of sodium chloride and chlorine, and at the last meeting of the Chemical Society read a further paper on the subject, the results therein being confirmatory of those previously published. It is shown that when isoamylic oxide is nearly saturated with hydrogen chloride at temperatures between 0deg. and 25deg., no appreciable interaction takes place, the values obtained by direct weighing agreeing with those afforded by titration with alkali; action takes place only very slowly between the two substances at ordinary temperatures. Hydrogen bromide acts far more rapidly on isoamylic oxide. It is further shown that hydrogen chloride acts extremely slowly on ethylic and isoamylic alcohols at ordinary temperatures. Hydrogen chloride when dissolved in these alcohols has a higher molecular rotation than when dissolved in isoamylic oxide, the value being, however, less than that afforded by aqueous solutions, thus:

In aqueous solution	4·300
In alcoholic solution...........................	3·324
In isoamylic oxide	2·245

The molecular magnetic rotation of sodium chloride was found to be 4·080 in the solid state, and 4·068 in aqueous solution. The value obtained for chlorine, using a solution in carbon tetrachloride, was 2·188, which is considerably higher than the value calculated from compounds such as propyl chloride (1·733).

The New Pacific Cable.—In the House of Commons, on the 14th inst., Mr. Henniker Heaton asked the Under-Secretary of State for the Colonies whether he was aware that a contract was entered into last year, and now completed, between a French cable construction company and the Governments of New South Wales and Queensland for the construction of the first section, from Queensland to New Caledonia, of a proposed Pacific cable to America; whether he was aware that the French Government contributed two-thirds of the subsidy (the remaining one-third having been contributed by the British colonies aforesaid) on the binding condition that the cable material should be constructed in France, that only French officers and men should be employed to undertake the management and working of the cable during a period of 30 years; whether any remonstrance on the subject had been made to the Governments of New South Wales and Queensland by the Secretary of State for the Colonies; and whether he had any objection to state the nature of the reply from the Prime Minister of Queensland to Lord Ripon's communication? In reply, Mr. Buxton stated that the answer to the first three questions was in the affirmative. With regard to the last question, he said that a reply had been received from the Prime Minister of Queensland, in which he pointed out that the cable in question would enable the authorities to prevent much more easily the escape of French criminals from New Caledonia, this being a matter in which the Australian colonies were greatly interested.

Power Supply.—At last Tuesday's meeting of the Institution of Civil Engineers, Mr. Ellington read a paper on the "Hydraulic Power Supply of London," and the question of plant efficiency formed an important section of the paper. This is one of the ever-recurring problems in electrical engineering work, and thus comparisons were made. In the part of the paper dealing with plant efficiency the author discussed the question whether a combination of power supply during the day and the use of the energy for electric lighting during the night would improve the load factor, and arrived at the conclusion that little or no advantage in this respect was to be gained by such combination. The load factor of the hydraulic supply for the year 1887 was 0·275. For 1889, 0·338, and for 1892, 0·326. It was pointed out that the improvement of the load factors in recent years over 1887 was due to the enlarged area of supply, and not to the increased quantity of power supplied—the time of maximum demand varying in the different districts supplied. Load diagrams were given of the electric supply on December 21, 1892 (a foggy day) in Westminster, and of the hydraulic supply on the same day, and the two were combined. The load factor for the combined curve was 0·522, while the electric load factor alone was 0·533 and the hydraulic load factor 0·495. It was further pointed out that under the most favourable conditions a supply approaching the maximum would only be given on 280 days in the course of a year, and that it was impossible without storage to obtain from any combination of supplies more than 12 hours' work out of 24—a condition which would only produce a load factor of 0·380 against 0·325 actually realised. A low load factor was likely, therefore, to be a permanent cause of low efficiency in all methods of supplying energy which did not admit of extensive storage. The load factor had, however, a far greater influence upon the amount of capital outlay per unit of output than it had upon the cost of fuel and station expenses.

Self-Induction.—This title for an article appearing over the well-known initials "J. S.," in last week's *Industries*, was particularly interesting, as a long letter on the same subject was then under consideration. We only hope that "J. S." has made his text clear; we fear he has not. At any rate, "J. S." is not averse to progress, and would have consistency—but the latter he cannot have. He, although bold, cannot afford to do more than tinker. He, as are all those of the same persuasion, is compelled to take things pretty much as they are, and destroy a little here and there in order to construct a little. He would not get half-a-dozen readers or hearers were he to give full scope to reconstruction views. We trust we may be permitted to give a rather long extract from the article mentioned, which seems to embody its author's views. It says: "An electric circuit has unit self-induction when if the current increases at a rate of an ampere per second, there is a back E.M.F. of one volt. Thus if the current increases uniformly from zero to one ampere in a second, there is a back pressure of one volt, which means that if there is one turn of exciting wire, 10^8 lines of induction must have cut it in this second. If there are 100 turns of wire there must be 10^6 lines, and so on. A self induction of a henry may therefore be also defined as such, that if there is one ampere the product of the turns by the total induction enclosed by each of them is 10^8. It will thus be seen that magnetic reluctance and self induction are very closely related. Magnetic reluctance considers the magnetic circuit only, while self-induction consider the number of turns of wire in the coil, too. If the magnetic reluctance is taken as the magnetic potential divided by the total induction, it is the reciprocal of the self-induction where there is only one turn of exciting wire. The self-induction, however, varies as the square of the turns of wire in the exciting coil. For instance, if there are two turns instead of one, one ampere gives two ampere-turns, and therefore twice as much total induction, and the growing induction cuts twice as many turns. The current, increasing at a given rate, therefore generates four times the counter-pressure. There is thus a simple relation between self-induction and magnetic reluctance. The self induction is the reciprocal of the magnetic reluctance multiplied by the square of the turns in the coil."

Military Signalling.—Colonel G. E. Gouraud read a paper last Friday on the "Telephotos," a new means of electrical signalling by night and day. It is the invention of Mr. Claudius Victor Boughton, of Buffalo, N.Y. Colonel Gouraud said that signalling by flags had not made any remarkable progress since the day of the historic signal at Trafalgar. The night signals of Admiral Colomb had done and were still doing most efficient service in some ships which were not provided with electricity, and ships having command of a current and provided with mast-head electric lights effected a saving of time in displaying Admiral Colomb's time flash, with the obvious result that the increased brilliancy of the light carried with it the power of communicating to a greater distance. The theory of the telephotos was the production by electricity upon a shaft of incandescent lamps of any candle-power of the symbols of the Morse alphabet and numerals, in dashes of 5ft. length, made with 10 lighted lamps, and dots of 3in. made with one lighted lamp, and with unlighted intervals of 5ft. between each, which would bring under the eye the complete symbol at once, and was intended for use at any points within vision between which the laying of telegraph wires was impossible or impracticable. The telephotos was a combination of electrical connections contained in a case mounted on a pedestal which was fastened to the floor, having a key-board of the alphabet and numerals, like that of a typewriting machine, and the keys had raised on their underside all the Morse characters in brass, with platinum points; the crossbars, 106 in number, were flexible and embedded in hard rubber. A groove under the keys contained a number of fine steel bicycle balls, with $\frac{1}{16}$in. of lost motion, which was the thickness of a key, so that when that space was occupied by pressing one key down between the balls all other keys were locked. The key, when pressed down, came into contact with, and conveyed the current to, the crossbar by means of the raised symbol on the underside of the key, from which crossbar wires led to the lamps on the light frame, which when lighted made the Morse character corresponding to that on the key pressed down. The switchboard was 11in. by 14in., and had a capacity of controlling perfectly 106 incandescent lamps. The lamp was one of an entirely new design, representing in shape a round door-knob, with a filament of 10 coils placed crosswise in order to secure the greatest light surface for the lamp; each lamp fitted into a parabolic metal reflector, and the front of each was covered with a paralleling lens, designed at the Cornell University for this invention. Without in the least decrying the importance of either the telegraph or telephone in field service, Colonel Gouraud expressed his opinion that the telephotos would accomplish what neither of these systems could—namely, free communication along the coast between land and sea forces acting together. It could move side by side with an army in its strategic changes of position, and within vision limits by day or night be doing good work long before wires could be laid to operate either telegraph or telephone.

THOMAS PARKER.

Mr Thomas Parker, J.P., F.R.S. Edin., M.I.C.E., M.I.E.E., M.I.M.E., was born in 1843 at Lincoln Hill, near Coalbrookdale, Shropshire. The education he received when a boy was very limited, as at the age of nine years he was obliged to go to work with his father, a moulder at the Coalbrookdale Ironworks, where he continued for eight or nine years, doing the commonest and hardest work connected with the primitive method then in vogue of smelting small quantities of pig iron in little cupolas, and transferring the metal from the cupolas to the moulding shop. On leaving Coalbrookdale, Mr. Parker removed to Birmingham, thence to the Potteries, and subsequently to Manchester, where he had some means of getting the education which he failed to obtain in his earlier days. Electricity was at that time, 1863-4, beginning to be talked of as having an important future of its own, and Mr. Parker, always studious and inventive, resolved, so far as he could, to master this mysterious subject. Science, however, was only taught to those who could well afford to pay for it, and it was not likely to open its treasures to a poor youth whose only recommendation was a determination to learn, even without the very desirable preliminary of a good ordinary education. His attention was accidentally directed while at Manchester at this time to the lectures of Sir Henry (then Professor) Roscoe and others at the Hulme Town Hall, through which he soon obtained considerable proficiency. The advantage he received from Sir Henry Roscoe's lectures was supplemented on his removal to Birmingham by a course of study at the Midland Institute, which was then only recently established, but which has since been so important a factor in the educational and scientific progress of the Midlands. Mr. Parker afterwards returned to his old quarters at Coalbrookdale, where he had the offer from his former employers of a responsible position, and where he remained seven years, devising several inventions, including, amongst others, the Parker-Weston steam pump and the "Kyrle" grate, for which he received a silver medal at the Smoke Abatement Exhibition. From being himself a scientific student, Mr. Parker soon developed into a science teacher, and he gave many popular lectures in his own neighbourhood concerning the multifarious applications of the new power then claiming public attention. It was at one of these lectures that he met with his future partner, Mr. Bedford Elwell. In 1882 he founded the Elwell-Parker firm, manufacturing various electrical appliances, and at about the same time took out a patent for storage batteries or accumulators. Shortly afterwards the Elwell-Parker dynamo was invented and introduced. The first of these dynamos sold was sent to Manchester for use in depositing copper upon calico-printing rolls, and the success of this machine speedily brought orders for more. The firm at this period only employed three individuals—viz., Mr. Parker himself, a man, and a boy. Mr. Parker then became connected with the late Mr. Charles Moseley, of Manchester, Elwell Parker, Limited, being formed, with Mr. Moseley as chairman. Orders then came so quickly that the company was obliged to build new shops and greatly extend the works in Commercial-road, Wolverhampton, where special facilities had to be provided for the ever increasing demand, and this increasing business it was that finally led the firm, after it had been taken over with other concerns by the Electric Construction Corporation, to choose a large piece of land at Bushbury, a mile and a half to the north of Wolverhampton, on the Stafford road, where it is in close proximity to the London and North-Western Railway system, with which the works are connected by a special siding. The factory itself has, under the guidance of Mr. Parker, been fitted completely with the most modern tools for the production of heavy electrical plant, and lighter tools and delicate machinery for the production of other goods in connection with the trade. About 700 men are now employed at these works. Mr. Parker has taken out a great number of very valuable patents in connection with electricity, and has been engaged upon some of the greatest electrical undertakings in this country and abroad, and has been connected with more schemes for electrical traction than any man in England, the Electrical Construction Corporation under his guidance having carried out most of the tramways and railways using electricity as the motive power, including Blackpool, Birmingham Central, South Staffordshire, Madras (India), and the Liverpool Overhead Railway, this latter being the greatest engineering feat that has ever been attempted in this direction. Mr. Parker is justice of the peace for Wolverhampton, a member of the Royal Society of Edinburgh, Civil Engineers, Electrical Engineers, and Mechanical Engineers.

POLYPHASE ALTERNATE CURRENTS.

(Concluded from page 562.)

MOTOR FORMULÆ.

When an attempt is made to arrive at an exact and complete theory of these machines from which we may derive definite formulæ for constructing the various component parts, in order to yield a given result, we are met at once with several points as to which we can only make assumptions, and to get over the difficulty we must give arbitrary values to the efficiency, specific induction, etc., of any particular machine in question. The nature of the current actuating the motor must also be defined; and, finally, one particular type of machine chosen.

It seems almost impossible, therefore, to arrive at any calculation of this kind that shall be absolutely general.

This is true when we consider any electrical machine whatever, and it is only when we have to construct a motor of a type well known and constantly in use that there becomes available a large number of practical facts which may help in assigning values to the characteristics not fully determined. In such a case, when fair values are given to the efficiency and special dimensions, we may feel sure that after the machine has been built, it will work in the desired manner, under the conditions arranged for.

Owing, however, to the extremely small number of polyphase motors actually constructed and in use to-day, there is a corresponding paucity of facts and experience with regard to the values to be assigned in our equations to the indeterminates. We might, perhaps, institute comparisons with motors of a continuous-current or synchronous alternating-current type, as already in use, and with alternating-current transformers, keeping well in sight meantime the conditions that theory indicates to be the most suitable and proper. If, however, this kind of speculation—interesting as it undoubtedly is—may effect any tangible result, it can only be with the aid of a supplementary series of practical experiments undertaken as soon as possible. The following expressions, therefore, must only be regarded as indicating a direction rather than an exact path; although in themselves they may not be very far wrong, yet they have not been so far sanctioned or confirmed by practice. If A represents the total power or input, it may be expressed as being equal to $\omega_2 G \times \eta \times k$, where ω_2 = angular velocity of armature, G = total couple, η = efficiency (representing practically the electrical losses in the armature), and k = the mechanical friction losses, together with losses due to hysteresis and Foucault currents—*i.e.*, the magnetic waste. This is, or ought to be, not more than 5 per cent., so that $k = \cdot 95$.

The machine in question is considered to be of the bipolar type. In the equation $A = \omega_2 G \times \eta \times k$ the value of G, previously given, may be substituted, whence we have:

$$\frac{A}{\eta . k} = \frac{p}{2} \frac{\omega_2 N}{l} \frac{\omega^2 l^2}{\omega^2 l^2 + r^2}.$$

We can replace p, l, and N by their values in terms of the motor dimensions, and thence obtain the latter. The magnetic resistance, R, is first worked out. If y = radius of armature, z = its length parallel with the axle, x = thickness of core, and δ = width of air-space, then the magnetic resistance of the air-space is given by the expression $\frac{4\,\delta}{\pi\,y\,z}$, allowing a space equal to the air-gap width between the periphery of armature core and the holes pierced through the latter for the winding.

The total resistance of the machine may be averaged as being equal to 1·25 that of the air-space, so that

$$R = \frac{5\,\delta}{\pi\,y\,z};$$

but, as has been stated,

$$l = \frac{2\,\pi\,p}{R},$$

whence

$$\frac{2\,p}{l} = \frac{5\,\delta}{\pi^2\,y\,z} = \cdot 5066\,\frac{\delta}{y\,z}.$$

If I is the specific induction in the armature, we have

$$N = 2\,(\cdot 8\,x\,z\,I),$$

in which expression the use of the coefficient ·8 assumes that we have an armature core of laminated sheets insulated one from the other, so that an allowance has to be made for the reduction in volume of iron.

We may now rewrite our first expression thus:

$$\frac{A}{\eta\,k} = \frac{5\,\delta}{4\,\pi^2}\,m\,\omega_2\,(1\cdot 6\ I)^2\,\frac{x^2\,z}{y},\ \text{where}\ m = \frac{\omega^2}{\omega^2 + \frac{r^2}{l^2}}.$$

A very small value—say, 2mm.—may be given to δ, because the sunk winding enables the armature to run more closely to the polar faces than with exterior winding; and a value of, say, 10,000 may be given to I. From the above equation may, therefore, be deduced at once the value of $\frac{x^2\,z}{y}$, all the other components being known or obtainable from expressions previously given; and we thus have a section of the armature in a plane parallel with its axle. Its form, however, is still undetermined; and practical considerations must govern this—such as the minimum amount of cooling surface, maximum peripheral velocity for the armature, etc. In any case limits are given to the dimensions of the armature whether it be of the ring or the drum type (in which latter case, of course, $x = y$).

To determine the size of winding, we may take an armature of the type shown in the last article, where a single coil is formed of two bars of a length, z, and section, s, and two circles or rings at the ends of $2\,y$ diameter, and $\frac{s}{2}$ section, taken out of the entire mass of the copper end rings, whose total section in each case would be $\frac{p\,s}{2}$.

The resistance, r, of each coil

$$= 2\,\frac{z}{s}\,\rho + 2\left(\frac{\frac{1}{2}\,\frac{\pi\,y}{s}\,\rho}{2}\right) = \frac{2\,\rho}{s}\,(z + \pi\,y),$$

where ρ = the specific resistance of the copper employed.

It has been shown, however, that

$$\frac{r}{l} = \frac{\omega_2\,(1-\eta)}{\eta},\ \text{and}\ l = \frac{2\,\pi\,p}{R},$$

therefore

$$\frac{2\,\rho}{s}\,(z + \pi\,y) = \frac{\omega_2\,(1-\eta)}{\eta}\,\frac{2\,\pi\,p}{R};$$

whence

$$p\,s = \rho\,\frac{R}{\pi}\,(z + \pi\,y)\,\frac{\eta}{\omega_2\,(1-\eta)}.$$

We may assume a value for p contingent upon a result for s which shall agree with the armature dimensions already given.

Field Excitation.—We may assume a triphase winding with q coils upon each magnet. Then N, the total flow, may be proved equal to $\frac{\pi^2\,y\,z}{5\,\delta}\,q\,C$, where δ = width of air-gap, and C = strength of current in one of the windings. But N has been shown equal to $1\cdot 6\,x\,z\,I$, and I is given. Hence we have—

$$1\cdot 6\,x\,z\,I = \frac{\pi^2\,y\,z}{5\,\delta}\,q\,C,$$

and

$$q\,C = \cdot 8105\,I\,\delta\,\frac{x}{y}.$$

This result, however, gives no more than the number of ampere-turns required for the proper excitation. C and q must be individully assumed and trials made until values are obtained consonant with the other results and the general conditions of working.

Coefficient of Self-Induction in the Field Circuit.—This may be obtained from the expression,

$$q\,\frac{12\,q}{R}\,\sin\frac{\pi}{3},$$

and since R may be shown equal to $\frac{30\,\delta}{\pi\,y\,z}$, we have

λ (or coefficient of self-induction)

$$= \frac{\sqrt{3}}{5}\,q^2\,\frac{\pi\,y\,z}{\delta} = 1\cdot 089\ q^2\,\frac{y\,z}{\delta}.$$

TRANSFORMING POLYPHASE ALTERNATE CURRENTS INTO CONTINUOUS CURRENTS.

If we send through the armature of a continuous-current machine, alternating currents differing in phase (if, for example, triphase currents are thus employed, entering at points in the winding placed at 120deg. from each other), there results, as we have already seen, a rotary magnetic field. If, therefore, this armature is placed in a magnetic field, N S (see Fig. 23), of constant strength produced by any suitable means whatever, it will rotate in the ratio of one turn per period.

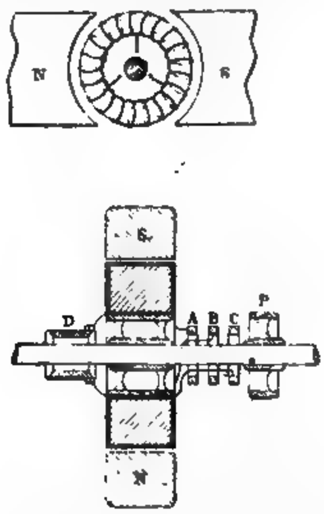

FIG. 23.

Suppose, now, that on the same spindle and in the same field, N S, is mounted the armature of a continuous-current machine, evidently at the brushes of the second armature we may derive a continuous current. The two windings may be placed on the same armature, or, further, there may only be a single winding, arranged as shown in the illustration (Dobrowolski).

The armature is mounted between the two pole-pieces, N S. It is wound in the usual fashion for continuous-current working, the coils being connected to the commutator, D. At three points in the winding—120deg. apart—a connection is also made with each of the three collecting rings, A, B, C. P is the driving pulley.

An appliance of this kind may be operated in any of at least six different methods:

1. Continuous current motor.
2. Synchronous triphase alternating-current motor.
3. Continuous-current generator.
4. Triphase alternating-current generator.
5. Transformer of continuous into triphase alternating currents.
6. Transformer of triphase alternating into continuous currents.

The last development alone need here be touched upon.

It is plain that by the use of a single winding, or of two windings upon the same armature, the efficiency of the machine is much greater than when we have two armatures upon the same spindle. In the former case, the mutual induction of the two circuits puts self induction to a profitable use. To employ two windings, moreover, allows the E.M.F.'s to be varied in any desired ratio, whilst with a single winding the ratio is constant.

In the annexed illustration, Fig. 24, is shown the scheme of a ring armature winding divided into three sections of 120deg., through which triphase currents are passed; but, of course, similar methods of working out the details would apply in the case of a rotary field produced by any number of displaced currents, or by the use of any arrangements such as those already described.

Fig. 24.

In a transformation of this kind the triphase rotary field, placed in a constant magnetic field, N S, is in reality fixed in space, and it is the armature which rotates synchronously with the period of the alternating currents employed,

$$\omega_1 = \frac{2\pi}{T}.$$

In this case the brushes through which passes the continuous current are fixed.

It may be shown that if k is the efficiency of the ring, the continuous current will have a strength

$$\gamma = k c = k \frac{3}{2} \sqrt{3} \frac{P}{Q} C,$$

where P = total number of wire turns, Q = number of wire turns through which the continuous current passes, and C = maximum strength of current in any section. The corresponding E.M.F. will be given by the relation $E = n_1 Q N$, where N = total flow from one pole to the other, n_1 = number of revolutions per second (if the rotary field is bipolar as we have so far assumed, then $\omega_1 = 2 \pi n_1$).

The power developed is $E \gamma = k n_1 N \frac{3}{2} \sqrt{3} P C$.

It may be noted that N depends both on the strength of the field, N S, and that of the field due to the triphase currents. Evidently we may suppress the exterior field, N S, and only present at each instant to the flow of the rotary field a magnetic circuit through which it can be closed on itself.

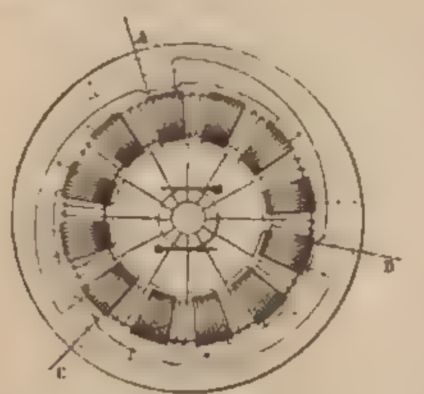

Fig. 25.

In the arrangement shown in Fig. 25, the magnetic circuit is closed by a ring exterior to the armature. The consequence is, that at each instant the flow has a path along which to close itself. The whole appliance is fixed, and the brushes alone turn round with a speed synchronous to that of the rotary field. This action is easily obtained by means of a small synchronous alternating-current motor.

All the windings already described—which allow of obtaining a rotary field (bipolar)—can be thus employed. In the illustration, a 12-coil winding is supposed to be used.

ON INSULATION AND FAULT DETECTION IN THREE-WIRE SYSTEMS *

BY WM. ROWAN WILSON, B.SC.

This paper is an attempt to show how the tests and processes which apply to other simpler systems work out when applied to the three-wire system, and to describe shortly the practice at the Glasgow Corporation electric lighting station, some of the processes being, I believe, novel. A good number of preliminary trials have been made in various directions, both in the laboratory at Waterloo street and also outside, in the streets, under the supervision of Mr. Arnot, the chief engineer. But passing over these, without touching on past successes or failures, we are led to consider first the apparatus used for giving at a glance the state of the insulation of the mains, etc., at any moment. This consists of two of Lord Kelvin's vertical multicellular voltmeters, one of which is joined from the positive of the street conductors to earth, and the other from the negative to earth. There are thus two electrostatic voltmeters in series across the 200 volts, and their "common point," so to speak, is joined to earth. The middle, or neutral, wire does not directly come into the apparatus at all. Suppose the system to be clear of faults, the voltmeters will be found to read nearly 100 each, but not usually exactly 100—*e.g.*, one might be 80 and the other 120. If now the positive becomes earthed, the positive voltmeter will fall to nearly nothing, and the negative one rises to nearly 200 (of course the sum of the readings must be 200). Or, suppose an earth on the middle wire, the voltmeters will both come to 100 exactly. We thus know at once when and on what main a fault arises; and although the apparatus is, as will be seen later, solely a recorder of the ratios of the insulations to each other, it is quite sufficient for the purpose for which it is designed. To calculate the absolute insulation of each main the voltmeter readings are taken as above, and also the current leakage from each two wires, by connecting the other through a very low-resistance ammeter to earth. There are thus obtained three current readings on the ammeter, as follows:

C = current through ammeter joined from positive to earth.
D = " " " " middle "
E = " " " " negative "

Call for the sake of calculation—

x insulation of positive main from earth.
y " middle " "
z " negative " "

And—

P difference of potential between positive and earth.
Q " " " middle "
S " " " negative "

By Ohm's law—

$$C = \frac{200}{z} + \frac{100}{y}$$

$$E = \frac{200}{x} + \frac{100}{y}$$

$$\therefore C \sim E = \frac{200}{x} \sim \frac{200}{z}$$

As we do not know which of the two, C or E, is greater, put symbol $\sim$

$$\therefore \frac{C \sim E}{2} = \frac{100}{x} \sim \frac{100}{z}.$$

$$\text{Also} \quad D = \frac{100}{x} \sim \frac{100}{z}.$$

$$\therefore \quad D = \frac{C \sim E}{2}.$$

Suppose a resistance put in parallel with the greater of the two insulations, x and z—*i.e.*, let a resistance be joined from the positive or negative to earth and varied till D = 0.

This resistance evidently would be $\frac{100}{D} = \frac{200}{C \sim E}$; but the experiment can be tried.

Then, it is evident that when this is done we make

* Paper read before the Physical Society of Glasgow University

positive insulation (for the time) equal to negative insulation (for the time being); see equation for D when D = 0.

Suppose for clearness $x > z$. Then

$$z = \frac{\frac{100}{D} x}{\frac{100}{D} + x}, \text{ i.e. } (z = x \text{ and } \tfrac{100}{D} \text{ in parallel}).$$

This gives a relation between z and x.

Now consider the voltmeter readings, P, Q, and S, and suppose for the moment the insulation of the neutral wire pretty good (this would at once appear from the ammeter tests, and if it were not good, the calculation is quite superfluous). We have a leakage current running from positive main to negative *viâ* earth equal to $\frac{200}{x + z}$, and if $x > z$ we have a leakage from the neutral to the negative *viâ* earth equal to $\frac{100}{y + z}$.

Of these two leakage currents the former is greater than the latter, and the method, for rough calculations, is to neglect the latter, and in the result make a percentage correction to allow for the error so introduced. However, the correction is unnecessary, because as the insulation varies so much the results are only within 10 per cent. no matter how much care is taken, and the correction would not exceed this unless there were a fault on the neutral wire.

The reading P on the voltmeter is the fall of potential due to current $\left(\frac{200}{x+z}\right)$ above, in the resistance x; and the reading S is the fall due to both leakage currents $\frac{200}{x+z}$ and $\frac{100}{y+z}$, which go in the same direction through z. If, as above stated, the smaller be neglected,

$$S = \frac{200}{x+z} \cdot z;$$

also

$$P = \frac{200}{x+z} x;$$

$$\therefore \frac{S}{P} = \frac{z}{x}.$$

But as above

$$z = \frac{\frac{100}{D} x}{\frac{100 + Dx}{D}},$$

$$\therefore \frac{Sx}{P} = \frac{100x}{100 + Dx};$$

$$\therefore DSx^2 + 100Sx = 100Px;$$

$$\therefore DSx + 100S = 100P;$$

$$\therefore \quad x = \frac{100P - 100S}{DS}.$$

This deals only with constants which have been obtained, and ∴ gives x. y and z are obtained from the former equations.

For instance, take the following case:

P = 120	C = 3·5
Q = 20	D = 0·5
S = 80	E = 2·5

$$\therefore x = \frac{100(120 - 80)}{\frac{1}{2} \cdot 80}$$

$$= 100.$$

also

$$\frac{x}{z} = \frac{120}{80} \quad \therefore z = 67,$$

and putting in

$$2{\cdot}5 = \frac{200}{100} + \frac{100}{y}.$$

$$\therefore y = 200.$$

These results show the tendency noted by Prof Kennedy of the negative main to go towards earth (so to speak). This method is simple and quite accurate enough for the purpose. The insulation is roughly calculated in this way each morning at Waterloo-street station, and the results are noted. Of course, the symbols take away from the apparent simplicity and make the process longer. The whole experiment really takes about three minutes in practice. Also, approximate results only are tried for, as the insulation varies so much each instant that, in spite of the utmost speed being used, the values may change 10 per cent. before the end of the experiment, and, therefore, as pointed out above, an approximate method of calculation is quite good enough.

All the constants have been, at times of comparative rest, obtained by Lord Kelvin's balances and voltmeters, but, for the above reason, this is scarcely worth the trouble.

With regard to insulation, the Corporation of Glasgow insists on 60 megohms per lamp from its customers, and the mains are fully up to this standard, the state of the weather seeming to make absolutely no difference in the insulation so far as can be judged.

With regard to the instruments used, the voltmeter must be electrostatic, as if current-using instruments be used we have really only a modification of the celebrated "lamp test," which, although everyone does not know it, for a large network of mains is of no real value except to mislead the public, for which purpose I have heard that it is frequently used both in London and elsewhere; for instance, if the insulation be very low, all round, in comparison with the resistance of a lamp, the lamp will not glow unless there be one or more heavy faults on the mains, although the current leakage would in this case be somewhat large.

In finding out faults, the method at first used was to divide the city network into five districts, and feed each from a feeder. This was done at a time of light load. The ammeter is joined from the good main to earth, and gives a fairly large reading (if too large half an ohm or so of resistance is put in), and the feeders are separately drawn for a moment. On drawing a certain one, the pointer of the ammeter falls to near zero, and the fault must be in the district from which the current was cut off. This narrows the search to a feeder and a mile or so of network, and this had to be gone over with an ordinary detector after cutting the current off from the district.

In practice, however, a method is required which renders the disconnections of sections of network, always a troublesome task, unnecessary. This is achieved in the following manner. A pocket compass is taken to the manhole where the feeders leave the station, and laid on one of the feeders on the side of the system on which the fault lies. The needle is then brought parallel to the conductor on which it lies by means of a strong bar magnet, which serves also to render less important any changes in the magnetic field around due to varying currents in the other feeders.

The needle having come to rest, the other side of the system is momentarily earthed; this causes current to flow through the feeder to the fault, and by earth to the other main. The direction and, roughly, the magnitude of the current flowing are known by the throw of the compass needle.

There are now two possible considerations: (1) should the current-flow point to a fault inside the station, and (2) should the flow point to a fault outside. The first case is obviously easily dealt with, as it is really only a simple form of the second case, and, in case of any difficulty, can be followed out in the same manner. In the second case the compass is applied to each feeder separately, and that on which the largest current goes to the fault, noted. The compass is then taken to the feeding point of that feeder and applied in a manhole. There are, as a rule, three or four lines of network leaving each feeding point, and the line which carries the heaviest current to the fault is easily found; this is then followed, tests being made at each manhole with the compass, and the heaviest earth-seeking current always followed till a point is reached where the direction of the earth-seeking current is seen to be reversed. The fault must lie between this and the last manhole at which the test was made, and this at once narrows down the field to be searched to a single line, at most, 100 yards long. The second instrument is now brought into use, but before describing this it should be noticed that there is a possibility of the fault being upon the feeder in question,

in which case the earth-seeking current will be found to come back from the network along the feeder, and we have the same case as above—a line of a certain length with a fault in it.

The appliance referred to which is now to be used consists of a straight length of 20ft. of insulated wire having, from its ends, leads brought out at nearly right angles and joined to a telephone receiver. Thus there is a triangular circuit whose longest side is 20ft. and which contains a telephone. On laying the straight length parallel to a conductor and making a momentary current in that conductor, the telephone is heard to buzz. This being so, the method of finding faults by the apparatus is to join the faulty length of cable to the mains at one end only, and to periodically connect the good main to earth, say, each half-minute. A current now flows from the network, along the faulty cable to the fault, and back by earth on each momentary earthing of the good main. The straight length of inductor wire is laid parallel to the faulty cable at the end where the latter is connected to the mains. On each momentary earthing, the earth-seeking current causes a rustle in the telephone, and if the 20ft. inducing length be carried along, it is obvious that when the fault is passed, the noise ceases. By practice, the fault can be located to about a yard with this apparatus, and the only thing left to do is to dig up the ground and repair the faulty conductor. Of course, this use of the telephone also applies to the case of a fault in a feeder composed of a mile of armoured cable with no joints, and this method of working would, in such a case, save great expense. Also in a concentric system the compass would find a fault (or short-circuit) with ease, where every other method involves great trouble and cost. The current in such a case would affect the needle, because the outer conductor being earthed (or easily made so), the current in the inner conductor will be much the stronger, as it has only one path open to it, while that in the outer has several equally good. The telephone would also be applicable to this case, and the advantage claimed for the telephone is, of course, the method of using it with direct current, and avoiding all trouble with motor-generators, etc., on the streets, as when the alternate current is applied for the same end.

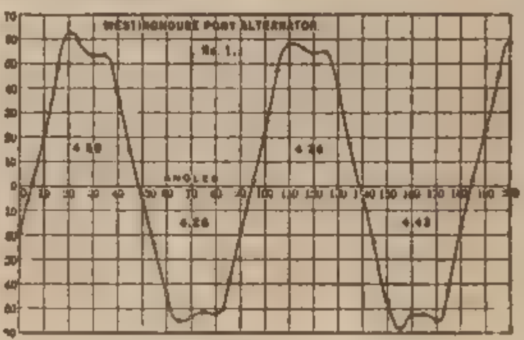
The appliances used for fault detection are, as appears, neither complicated nor expensive. The compass shows direction and, roughly, strength of current, but must be applied very close to the conductor. The telephone shows existence of current, but not direction, and may be 5ft. away from the conductor. The sensitiveness of these is such that faults under 10 ohms resistance can be found; this sensitiveness could be increased, but probably increased disturbance from the other mains would cause confusion, and a fault of greater insulation than 10 ohms can safely be left alone, as it will very soon get either worse or better.

Using these methods and apparatus, no difficulty has been experienced in keeping the mains at Glasgow free of permanent earths, and we consider that these embody all that is necessary for the keeping of a three-wire system of mains clear of leakage and its attendant evils.

IRREGULARITIES IN ALTERNATE - CURRENT CURVES.*

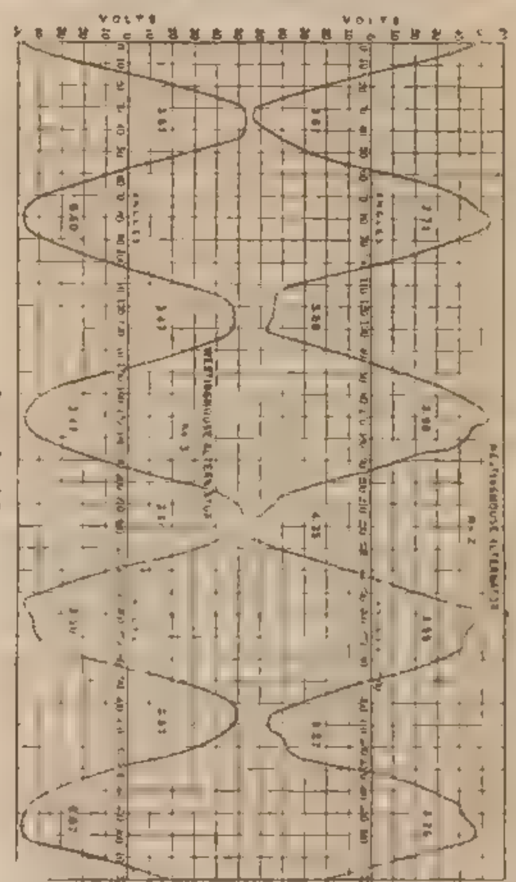
BY FREDERICK BEDELL, K. B. MILLER, AND G. F. WAGNER.

Curves of a more or less sinusoidal nature are commonly plotted to represent the instantaneous values of an alternating current, and various conclusions are drawn from their forms and relative positions. For any perfectly symmetrical generator the curves for successive periods are the same, both in shape and size, but decided differences may exist between the successive portions of the curves for machines which are not symmetrical. In the larger machines this difference is not likely to exceed 1 or 2 per cent., not introducing serious error into the mean results, although occasionally a greater difference may be found. In the smaller machines, however, the instantaneous curves show marked irregularities, so that to take one period as typical is not always justifiable.



Curve 1.

To investigate this point experimentally, Curves 1, 2, and 3 were taken from three small eight-pole Westinghouse alternators, showing the instantaneous values of the E.M.F. The E.M.F. was measured by means of a Thomson multicellular voltmeter connected around one of two incandescent lamps connected in series across the terminals of the machine, the whole E.M.F. being readily found by a proper calibration. The instantaneous reading was obtained by means of a revolving contact-maker on the shaft which made the contact at a definite point in the revolution of the armature, as indicated by a graduated disc. The three machines from which Curves 1, 2, and 3 were taken were



Curves 2 and 3

apparently alike in all respects. An inspection of the accompanying figures shows a decided difference in the curves from different machines, and also differences between successive periods of the same machine. This is further seen by comparing the areas of consecutive loops of the curves, as marked upon them. The resistance used was non-inductive, and whether the curves represent current or E.M.F. is merely a question of scale. In any case, the ordinates of the present curve represent the instantaneous values of the current, $i = \frac{dQ}{dt}$; and the area enclosed by the curve is $\int i\, dt = Q$—that is, the area enclosed by the current curve is proportioned to the quantity of electricity which flows, and for a complete cycle or revolution of the armature must be zero, inasmuch as there is no continual

* A paper read before the Madison meeting of the American Association for the Advancement of Science, August, 1893.

flow one way or the other. Likewise, the ordinates of the E.M.F. curve represent the instantaneous values of the E.M.F., $e = \frac{dN}{dt}$, and the area enclosed is proportional to the change in the number of lines of magnetisation through the armature. Evidently the algebraic sum of these areas must be zero for a complete cycle, since the magnetisation is the same at the beginning and end of a complete revolution of the armature. To establish this point experimentally, Curves 2 and 3 were taken, each for a complete revolution of the armature. In these curves, ordinates represent E.M.F., and abscissæ the portion of the cycle, with reference to the position of the armature at which readings were taken. The areas of these curves were obtained by a planimeter, and in arbitrary units are:

Areas, Curve No. 2 — Positive.	Negative.	Areas, Curve No. 3 — Positive.	Negative.
3·71	3·61	3·51	3·50
3·98	3·59	3·47	3·47
3·58	4·35	3·68	3·60
3·25	3·27	3·57	3·67
14·52	14·82	14·23	14·24
Total – ·30		Total – ·01	

Although, separately, the positive and negative areas widely differ, the sum of the positive and negative areas are very nearly equal, thus experimentally establishing the conclusion reached above.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE INSTITUTION COUNCIL.

The following letter was issued from the offices of the National Telephone Company, Limited, to the company's employés and others happening to be members and associates of the Institution of Electrical Engineers. The suggestion did not apparently meet with acceptance, since the nominee was not elected—a result not to be regretted, for the proceeding was in unquestionable bad taste, and the interference of a commercial company in the affairs of a technical institution is scarcely to be encouraged. The letter is as follows:

"National Telephone Company, Limited,
"London, E.C., December 8, 1893.

"Dear Sir,—You will probably have noticed that telegraph and telephone interests appear to have been over looked in the preparation of the Council list for next year. There is a strong feeling among telegraph and telephone men that they should be represented in the Council of the Institution. May I therefore suggest that the name of Mr. Dane Sinclair might very properly and usefully be substituted for one of the four names suggested by the Council, as Mr. Sinclair is an old telegraph man, and now engineer-in-chief to the National Telephone Company, Limited. Should this meet with your approval, perhaps you will kindly use your influence in this direction amongst your friends.

"Trusting you will pardon the suggestion, I am, yours faithfully, "THOMAS FLETCHER."

SHUNTS.

SIR,—The plaint of "H. L." has aroused my sympathy. His case is undoubtedly a sad one, but the confusion, or, to quote his own words, the "fool's paradise," in which he finds himself is possibly due to two causes—*i.e.*:

(1) The rule of thumb methods of old electricians; and
(2) Rule of thumb methods of modern engineers.

The word "shunt" had, of course, its origin in railway work, and 30 or 40 years ago sufficiently expressed the effect of introducing into an electrical circuit another circuit of lesser resistance. The phrase was familiar to all, and while there was and is a difference between a railway shunt (or, more properly, branch line) and a shunt electrical, the effect of both was apparently the same, and the comparison sufficed at that time for all practical purposes. Culley and the majority of his contemporaries taught that a shunt *diverted* current, as a rough rule to go by, but they must have known better, and I should be greatly surprised to hear that any practical electrician ever really credited so obvious an absurdity.

The question seems to me to be whether E is or is not constant. $C = \frac{E}{R}$, so that whatever changes are made in R no difference should be made in E, which is by implication unalterable. Let us see what Kempe says: "If we call C the current passing through the galvanometer without a shunt, then, on introducing the shunt, C will divide between the two resistances, the greater portion of the current going through the smaller resistance, and the smaller portion through the greater." This clearly points to *diverting* or *shunting* C, but not to altering E. But he also says: "the current which would flow through the galvanometer when the shunt was removed would be $\frac{\text{galvanometer} + \text{shunt}}{\text{shunt}}$ times the strength of the current which flows when the shunt is inserted. If *strength* in this case means intensity, it follows that E is alterable; if it does not mean intensity, it must at all events be due to alteration of pressure. Again, he says that the action of a shunt is to *reduce* the total resistance in the battery circuit, and so *increase* the strength of the current passing out of the battery. He says, in fact, that if we reduce R we increase the strength of C.

"If we employ very high resistances," says Kempe, "to measure a low resistance, a considerable alteration in the former would produce very little alteration in the current flowing through the galvanometer, *for the E.M.F. being constant*," etc. The italics are my own. Here we have a direct statement—and it has also been made by other writers—to the effect that E is unalterable, or, at all events, is unaltered, whereas we know that it must be alterable, and *is* altered. Ohm's law is inflexible. If it can be applied to one circuit, it can be applied to a thousand circuits. It is either correct or incorrect: and if we are to believe that E is constant, why the formula $E = CR$?

By $C = \frac{E}{R}$ we see that C is variable; by $E = CR$ we see that the resultant E is variable; and by $R = \frac{E}{C}$ we see that R is variable, but C would not be variable in a branch if E were constant. Let us, however, suppose, for the sake of argument, that E *is constant*, but let us call it *pressure*. If the pressure in a circuit were constant, a thousand shunts might be introduced without the slightest effect; the pressure would be as great on the galvanometer coils with as without the shunts. It is absurd to say that if the head of water in a vessel remained absolutely constant, the pressure exerted by it could be affected by a multiplication of channels, and it is equally absurd to propound the theory that electrical pressure being constant the multiplication of circuits can have any effect upon the current flowing in the original circuit. It is very convenient to consider E as a fixed quantity, but it does not follow that because it is convenient it is correct. It would be equally simple to consider C as a fixed quantity and deal only with the changes produced in E, but, as a matter of fact, R must vary both of them, and any alteration in the conductivity or resistance of a simple or compound circuit must produce a difference in pressure, and a consequent difference in the current flowing. Shunts, derived circuits, and parallel circuits, are all methods of relieving pressure. In other words, reducing R increases C, but increases it by opening the floodgates, and at the same time decreasing the head of pressure which had been acting upon them. The word "shunt" is in itself a misnomer. It should be called a "relief," or "sluice," or some other word which would more accurately express the theoretical effect of its action.

I will conclude with another example from Kempe. Speaking of the joint resistance of two or more parallel circuits, he says: "Two wires of equal conductivities, when joined parallel to one another, will evidently conduct twice as well as one of them; and in a like manner, *three* wires will conduct *three* times as well as one. Similarly, two wires, one of which has a conductivity of 2, will, when combined with one which has a conductivity of 1, produce a conductivity of 2 + 1 or

3. . . . Applying the foregoing law, the resistance between the terminals of the galvanometer before the introduction of the shunt being G, that on the introduction of the shunt will be $\frac{G\,S}{G+S}$." Where, Mr. Editor, does the *splitting* come in here? There is simply a large increase of area and conductivity due to the introduction of the shunt. No splitting can take place, and no change can be produced in the current flowing through the galvanometer, unless the pressure is relieved.—Yours, etc.,

SIDELIGHT.

SIR,—Perhaps I can assist your correspondent "H. L." The point that is omitted in the explanation of the action of shunts applied to galvanometers is that the E.M.F. at the terminals of the galvanometer is lowered by the passage of current which passes through the shunt, by reason of the charge made upon the initial E.M.F. for the passage of the current through the generator, whatever it may be, and the wires and other apparatus through which the current may pass on its way to the generator. If, to take a simple case, a cell or a number of cells of a given battery are connected directly to the terminals of a high-resistance galvanometer, the E.M.F. present at the terminals of the galvanometer is very nearly the full E.M.F. of the battery at the moment, because the current passing in the circuit and through the battery itself is very small, and therefore the charge for its passage, calculated from the formula $E = C\,R$, is also very small; E, in this case, being the fall of E.M.F. from the total E.M.F. generated in the battery; C, the current passing in the circuit; and R, the resistance of the battery and connecting wires. When a shunt is added, the factor C immediately increases, because the total resistance of the circuit has decreased in proportion to the well known law of derived circuits. C being increased, E, the charge for the passage of C through the resistance offered by the battery and connections, is also increased, and so the E.M.F. at the terminals of the galvanometer is decreased, and, of course, with it the current passing through the galvanometer coils.

When a shunt of very low resistance is applied to the galvanometer, practically no current passes through its coils, because the E.M.F. at its terminals is reduced to nil. Wherever this reasoning does not hold good, no shunting, in the sense that is usually understood, takes place. Thus, with a shunt-wound dynamo, the current passing in the shunt coils decreases as more current passes into the external circuit, not because of the lower resistance of this outer circuit, but because the E.M.F. at the terminals of the shunt coils is lowered, owing to the charge on the initial E.M.F. for the passage of the increased current through the armature coils.

Where the E.M.F. is maintained constant at the terminals of the dynamo as by the addition of the main coils, the current in the shunt actually increases as the current passing in the outer circuit increases, where the shunt coils are connected to the brushes.—Yours, etc.,

Cardiff Electrical Works. SYDNEY F. WALKER.

[We do not think our correspondent "H. L." is quite so puzzled as he makes out to be, but is rather on the growl at the time wasted in reading and hearing explanations that are false, and desirous of knowing what text-book will give him correct information. Of course, Mr. Walker fully understands that not one per thousand of students realises that his shunt to his galvanometer is not merely a by-path—or a diversion. Unfortunately, the books tell him it is when it is not. Mr. Walker sees "H. L.'s" point, while a contemporary, setting itself up as a caustic, really a flippant, critic, does not. This contemporary always reminds us of a certain squire whose mental imbecility was only equalled by his unparalleled conceit, to whom a critic suggested a subcutaneous injection of a concentrated essence of brains as a medicine much to be desired.—ED. *E. E.*]

NOZZLES USED IN FORCED DRAUGHT.

SIR,—A month or two since many of the technical journals, under the heading of "Duplex Nozzles," published certain disparaging statements as to the status of an old and tried friend—viz., the solid, simple, or central steam-jet as applied to blowing purposes. As strong conservatives in this matter, we ask you to allow us to reply on the other side.

Sir Wm. Siemens was, we believe, one of the first to claim higher efficiency for the annular over the central or solid steam-jet for blowing purposes. We had, however, supposed that no one in these days who had given the subject any practical consideration would now support the proposition. It should, however, be noticed in the first place that a nominally annular jet is not really so unless the air, or whatever other fluid is to be propelled, is admitted into the annulus through the centre, as in the blowers designed by Sir Wm. Siemens. In the duplex nozzle referred to above not only is no provision made for admitting air inside the annulus, but the annular jet itself acts as a shield to prevent access of air to the central or solid jet. This explains the advantage of the interrupted annulus of the duplex nozzle, the three or four jets in the ring allowing access of air to the central jet as well as all round themselves. We have made the subject of jet blowers a special study for the last 10 years, and with respect to the form of nozzle have come to the definite conclusion that the central or solid jet is the most efficient for all ordinary purposes, and that any departure from this not only increases the first cost and adds useless complications, but actually detracts from the efficiency.

Having these very decided opinions, we were rather surprised at the prominent position given in the technical Press to the alleged advantages claimed for the duplex nozzle. To leave no room for doubt, we obtained one of the duplex nozzles (as well as the combining tube supplied with it) and conducted a series of tests with it, the results of which we give below. The nozzle has a central jet $\frac{3}{32}$in. diameter, and three jets in a ring surrounding the central jet and having a variable opening, the full maximum area being equal to that of a solid jet of upwards of 7mm. diameter. The duplex nozzle was regulated so as to give the same effect as a solid central jet of 4mm. diameter, which is considerably larger than our average size. The size of nozzle—viz., 4mm.—was taken as a standard for comparison as being the size of nozzle in the third type of blower referred to later on. The position of the regulating screw in the duplex nozzle was found after making several tests with various forms and sizes of combining tubes giving equal volumes of outlet air at equal pressures. The air pressures tested were $\frac{3}{8}$in. water column, which may be taken as a normal ashpit pressure, 1in. water, and 2in. water. To arrive at the proportional efficiency of the nozzles, an air-receiver of a certain capacity was filled with cold dry air at 20lb. pressure above the atmosphere, and emptied first through the duplex nozzle, with the regulator in the proper position, and then through the simple nozzle. This was repeated several times, and it was found that the duplex nozzle reduced the pressure from 20lb. to 5lb. in 25 seconds, whereas the simple nozzle, giving the same effect, required 45 seconds. In other words, the duplex nozzle to give equal effect, required 80 per cent. more steam than the simple central nozzle.

We presume, however, that the efficiency of the nozzle as such is of secondary consideration, and that the really interesting question is as to the relative efficiency of the complete blowers. To ascertain this a series of experiments were made with the duplex nozzle and the combining tube supplied with it, with our own blowers of various sizes, and with a third form of blower which has recently been *en evidence*. The air pressures tested with were as mentioned above, $\frac{3}{8}$in., 1in., and 2in. water column, the corresponding steam pressures being 16lb., 42lb., and 70lb. above the atmosphere.

The net result of the series of experiments is to show that to do a given quantity of work, where our blower required a unit weight of steam, say 1lb., the duplex arrangement used between $2\frac{1}{4}$lb. and $3\frac{3}{4}$lb., and the third form of blower from 2lb. to $4\frac{3}{4}$lb.

As the question of forced or assisted draught is continuously coming more to the front, and as the steam-jet offers the simplest and, for the most purposes, the best form of blower, we think the figures given above should be of interest to many of your readers.—Yours, etc.,

THE INSTITUTION.

The annual meeting of the Institution last week brought out two questions which seem to be agitating the minds of some of the members. One of these relates to the constitution of the Council, the other to the work of the Institution. The latter is the easier to deal with. When the President stated that the report was open to discussion, and invited the members to criticise, one member rose up to complain that the Institution ought to, but did not, interfere in the purely commercial question of competitive prices in wiring. We cannot say we were surprised at the member's complaint, because some undoubtedly hold that the Institution should not only regulate prices, but find work for particular firms on their own terms. Perhaps the grumblers would like a little financial assistance as well, and for that purpose desire the run of the Institution's bank-book. How any reasonable man can expect an institution of the position of the Electrical Engineers to interfere in purely trade matters is beyond comprehension. Was not a special branch of the London Chamber of Commerce founded in order to discuss these trade difficulties, and if so, why has not the member desirous of mooting the subject brought it before the tribunal formed for the very purpose of considering, among other things, the amenities of competition? If the various firms will cut each other's throats, that fact calls for no interference from the Institution, but should be rather a matter for congratulation, in that, having got rid of a number of unbusinesslike men, the probability would be to create a better race of business men. The simple remedy for cutting prices is to leave such jobs severely alone. If the prices are really too low, the firms engaged in the practice must come to an end, and will come the sooner if their prices and bad workmanship are allowed full effect. However great our sympathy for those who would do good work at a proper cost, we cannot see how any institution or chamber of commerce can really prevent "cutting prices." The olden days of guilds are abolished, and now there exists nothing but a desire of keeping out of the bankruptcy court to keep up proper prices. At any rate, the Institution has nothing to do in the matter, and the question was hardly one that the Institution could notice. It seems very hard for firms who want to do good work that they are kept out because of firms who must intentionally tender at prices that prevent good materials or workmanship being used.

The composition of the Council is another matter, and legitimately brought forward. No doubt it is an honour to be proposed on that body, and as far as possible each branch of the profession should be represented thereon, and for our part we think most branches are so represented. It is not so many years ago that we had to urge the claims of others than telegraphists, and according to the critics the pendulum has swung too far, leaving "old-timers" and telephonists out in the cold. As for the latter, they scarcely deserve representation. They have added little or nothing to scientific or practical literature through the pages of the *Proceedings*—

and dumb animals are not wanted in the Institution. We have enough drones as it is; so that the outgoing Council is amply justified in not placing a representative drone upon its house list. The President, in answer to a question, referred to the difficulty of getting papers, and no doubt the Council does and must lean upon those sections of the members which provide papers, and these sections thus obtain larger representation than other sections like. Why not suggest an intellectual uprising amongst the telephonists and telegraphists? Send in a few good papers, show you do belong to the profession, and because of such activity demand representation. You will surely get it; but to ask proportional representation, and not to give assistance in carrying on the work of the Institution, is a little too much.

OBITUARY.

THE LATE WILLIAM HUBERT PARKER.

It is with great regret we have to record the death of William Hubert Parker, who was for many years our esteemed colleague. Mr. W. H. Parker was the son of the Rev. J. Parker, and belonged to one of the best-known Worcestershire families. He was educated at Bradfield College, afterwards at the School of Telegraphy, and entering the Eastern Telegraph Company's service he spent a probationary period at Porthcurnow. Subsequently coming to London he became assistant editor of the *Contract Journal*, and also assisted in the production of this paper. A large number of friends have met him in one or other of these capacities, and those who were intimately acquainted with him knew him to be one of the most able, painstaking, and conscientious of literary men. He endeared himself to those he met, and his loss will long be felt, not only by his own family, but by a wide circle of sorrowing friends. Mr. Parker has had a lengthy illness, and earlier in the year took a voyage to Tasmania, but with little benefit. On returning, he gradually became weaker, and died on Monday last.

WOODHOUSE AND RAWSON.

The summary of the statement of affairs on May 17, 1893, the date of the winding-up order, and the official observations thereon are now in the hands of creditors. This summary reaches to nearly 24 pages of closely printed matter, with tabular statements throughout, and is a statement which fully bears out all our criticisms about this Company's affairs. A close attention to this summary will show that the Company never had a chance of success, and was carried on in a most irregular manner. It would be a disgrace to commercial enterprise if the men who had the control of this business were ever permitted to run another commercial concern. Five companies were originally amalgamated. Into the history of these we need not enter. We would like, however, to point out that in the course of time no less than 11 people were connected with the directorate, of which number, from the table on page 3, we should gather that three never qualified for the position, and as they never received any directors' fees, there is nothing more to be said with regard to them. Of the others, Sir John Stokes had 51 ordinary shares, and received over £694 in director's fees; Sir Rawson W. Rawson had 70 ordinary shares, and received £1,493 odd in director's fees; Sir Edwd. Thornton had 50 ordinary shares, and received £241 in director's fees. These are no doubt all estimable gentlemen, but no one, reading from what has since transpired, can for a moment doubt but that they were figureheads upon the Board, and we may assume the managing director and the board of directors for all practical purposes was Mr. F. L. Rawson.

The summary refers to the original prospectus and the subsequent prospectuses which were from time to time issued. We may quote the following paragraphs:

"The official receiver has examined the profit and loss account of Woodhouse and Rawson, Limited, on which a profit of £21,440 is represented to have been made for the year ending June 30, 1888, and discovers that a large portion of the profit arose by reason of the assumed value of various interests in other companies. So doubtful was the real profit that the auditors prepared a special report, the concluding paragraph of which is as follows: 'The accounts are in accordance with the books of the Company, but it is obviously impossible for us to be responsible for the net profit, having regard to the nature of the assets and the Company's interest in many trading concerns not yet fully developed, and without Stock Exchange quotations of their shares.'

"A balance-sheet of Woodhouse and Rawson, Limited, as at June 30, 1889, and a profit and loss account for the year ending that date, were duly prepared, the latter showing an apparent profit of £78,222. 3s. 6d. The auditors do not appear to have been instructed to examine it until May of the succeeding year; their report is dated June 26, 1890, and the official receiver gathers therefrom that very grave doubts existed in their minds as to the reality of the profits, having regard to the sources (similar to those of the previous year) from which such profits were represented to be drawn.

"The official receiver has not seen the accounts in the liquidation of Woodhouse and Rawson, Limited (which commenced in September, 1889), and consequently has at present no means of informing himself precisely to what extent the said profits have been realised, but he believes it is the fact that a large portion of them was illusory, and it may be necessary hereafter to apply for an inspection of the said accounts. In this connection Mr. F. L. Rawson states that, although certain of the items treated as profit were not subsequently realised, the liquidators, on the other hand, received considerably more for their interest in the Elmore companies than was taken credit for.

"The businesses were taken over as from the 1st July, 1889; Woodhouse and Rawson, Limited (of which company the then directors and subsequent liquidators are stated to have been Sir John Stokes, K.C.B., Mr. Frederick Ashby, Mr. Albert Hoster, Mr. T. H. Lambert, and Mr. F. L. Rawson) were the promoters, and it is said that there were no intermediary vendors or profits. The expenses of the promotion and formation were paid by Woodhouse and Rawson, Limited, and are stated to have amounted to about £10,000.

"All the businesses are stated by Mr. F. L. Rawson to have been profitable prior to the amalgamation, with the exception of the Woodhouse and Rawson Electric Manufacturing Company, and the Woodhouse and Rawson Electric Contract and Maintenance Company.

"Mr. F. L. Rawson was connected in the capacity of a director with all the businesses except that of C. L. Baker and Co., Limited."

The terms for which the businesses were acquired are set out in detail. The total price as per agreement was £269,000, of which £109,778 was in cash, and the balance in debentures and ordinary and preference shares. A very important reference states that some of the vendors' shares were subsequently sold at prices varying, it is stated, from par to £2 by the persons to whom they were allotted. The valuation of the assets taken over for this amount, £345,230, but of this no less a sum than £159,265 was for patents, and £97,000 for goodwill. The summary then goes on to analyse more in detail the various issues for capital, and tabulates five other businesses which were acquired at a purchase price of £41,000, payable £15,929. 10s. in cash, the rest in debentures and preference shares.

Then follows a summary of the various balance sheets put forward by the said Company, with an analysis of these balance-sheets. Of that for the year ending June 30, 1890, the following paragraphs on page 11 speaks:

"Having regard to the facts above mentioned, it will be a matter for further consideration: (1) Whether the

directors were justified in treating certain of these profits as earned and divisible instead of placing them to a suspense account, pending the development of affairs? (2) Whether Mr. F. L. Rawson was entitled to be credited with the full amount of £13,775 above mentioned? (3) Whether the facts were fully before the shareholders when they consented to part, as hereafter mentioned, with the guarantee fund?

"As bearing upon these points it has to be kept in mind that the International Okonite Company was only registered in June, 1890, and its prospects could therefore only be conjectured when the balance-sheet and profit and loss account were prepared."

The remarks as to the balance sheet for the year ending July 31, 1891, may also be quoted in full, as may also the remarks on the profit and loss account.

"ACCOUNTS FOR YEAR ENDING JULY 31, 1891.

"(1) *Balance-sheet*

"It will be observed that during this year the dividend guarantee fund disappears from the Company's balance-sheet, it had previously ceased to be represented by specific securities. This alteration was effected at a meeting of shareholders held on January 9, 1891, when it was represented that the Company had attained to such a flourishing state that the retention of the fund was not necessary for the purpose required, the prospects as regards the payment of future dividends being quite satisfactory. In consideration of obtaining a settlement at the time, the vendors, who are said to have proposed this arrangement, offered to forego the purchase money to the extent of £12,000, and the shareholders, evidently being satisfied as to their position, and fearing their inability to pay the whole amount in cash in July, 1892, agreed to a settlement on these terms, the balance of the purchase-money (£63,000) being paid as to £12,278 in cash, and as to the remainder (£50,722) in 5½ per cent. debenture stock.

"In view of the Company's subsequent history, it is to be noted here that although the dividend guarantee fund of £75,000 was lying in the business without interest, a portion of it (£50,722) under this arrangement became immediately chargeable with interest at 5½ per cent., under which circumstances the rebate of £12,000 has been at least a doubtful advantage.

"The item 'sundry investments,' was made up of the following items:

	Value as per balance sheet.		
Austrian Elmore shares	£5,842	10	0
Foreign Elmore founders' shares	125	0	0
French Elmore shares	625	0	0
Austrian Elmore debenture stock	6,451	0	0
International Okonite debentures	26,000	0	0
" ordinary shares	11,696	0	0
" preference shares	5,255	5	0
Ward Electrical Car Company shares	2,000	0	0
French Elmore debenture stock	1,000	0	0
Sociedad Espanola shares	9,699	0	0
Epstein securities	35,145	0	0
Shares in Phœnix Trust Company	15,000	0	0
Debentures in J. and G. Thompson, Limited	500	0	0
	£119,338	15	0

"(2) *Profit and Loss Account.*

"The sum of £4,156. 19s. 9d. was written off patents.

"The 'gross income' includes the following items:

"(a) Premium on shares, etc., £3,933.

"(b) A sum of £14,975, being the assumed appreciation on shares in the Phœnix Trust Company. This latter company engaged with Woodhouse and Rawson United, Limited, to become responsible for the flotation of the French Elmore Company, and afterwards of the Austro-Hungarian Elmore Company, and later the American and Canadian Elmore Company. Woodhouse and Rawson United, Limited, promoted the companies; the Phœnix Trust agreed to underwrite the shares, and was, in fact, a company formed specially to work in conjunction with Woodhouse and Rawson United, Limited, in these matters. Mr. F. L. Rawson was one of the directors of the Phœnix Trust Company.

"In order to secure an interest in the profits of under-*writing*, the Company took 25 founders' shares in the Phœnix Trust Company, for which they paid £25. When the profit and loss account was made up, this asset was written up to the amount of £15,000, and the balance of £14,975 carried into profit and loss account. The reasons for this large appreciation have been furnished by Mr. F. L. Rawson to the official receiver; the Phœnix Trust Company went into liquidation in December, 1892. The interest of the Company in the Phœnix Trust Company still stands at £9,156 in the books, now only estimated to produce nil.

"(c) £12,000, the rebate received in respect of the repayment of the dividend guarantee fund.

"(d) A sum of £35,145, treated as profit, on the promotion of the Epstein Accumulator Company, the whole of which existed merely in the shape of securities of that company, which were then and still are, except as regards a trifling amount, unrealised. The position of the Epstein Company was then such that the value of its securities could only be conjectured; they are now estimated to produce £17,022. Mr. F. L. Rawson became a director of this company, which has never paid any dividends, and as to which some further information is given.

"(e) £2,000 for services rendered in the promotion of the Ward Electric Car Company, the whole of which was represented by 1,000 fully-paid £10 shares, represented to be of the value of £2 each, of which 750 are now estimated to produce £375.

"(f) A sum of £1,111. 13s. 9d. being the assumed profit in respect of the receipt from the Sociedad Española of 3,233 shares, which the Company valued at £3 per share, in settlement of a debt for work done, etc., of which the prime cost was £8,587 6s. 3d. (invoiced at £9,699). As will be observed hereafter, these shares are now estimated to produce £1,616.

"(g) A sum of £2,640, being an assumed profit in respect of certain assets acquired from Messrs. King, Masterman, and Terry, which were estimated as of greater value than the amount paid for them.

"(h) A number of shares in the French Elmore Company were handed over to the Company by the Phœnix Trust Company as their share of profits on the promotion, but the amount subsequently realised from the sale of them cannot be readily ascertained from the books. The French Elmore Company has paid no dividends, and is at present in liquidation, but a scheme of arrangement is under consideration.

"(i) £5,000 paid by the Phœnix Trust Company as the profit of Woodhouse and Rawson United, Limited, on the formation of the Austro-Hungarian Elmore Company. This amount consists of 2,000 Austrian Elmore shares, estimated at £2. 10s. each, of which company's shares the Company now hold 2,337, estimated to produce £584. Subsequently the Company received as commission on the sale of German Elmore patents £4,588 in Austrian Elmore 6 per cent. debenture stock, which was estimated at par, and is now estimated to realise at 50 per cent. discount. The Austrian Elmore Company has paid no dividends.

"The 'net profits' amounted to £35,103. 9s. 2d., which, together with £16,335. 15s. 3d. brought forward from the previous year, left an apparent sum of £51,439. 4s. 5d. for the directors to dispose of. A dividend of 8 per cent. on preference and 15 per cent. on ordinary shares was again paid for the year, and absorbed £31,408. 16s. 10d., in addition to which the reserve fund was increased by £10,000, the bad debt reserve by £1,500, and the employés pension fund by £500.

"The accounts for this year will also form the subject of further enquiry, particularly in connection with the question whether the directors were justified in declaring dividends out of profits which could only be estimated and were in such a large degree unrealised.

"The auditors' certificate on the accounts for this year stated that 'the amounts taken credit for, for plant, stock, and works in progress and investments not quoted, have been certified by the Company's officials.'

"Notwithstanding the alleged prosperity of the Company as described in the annual reports, it is the fact that about this time the directors found it necessary to have recourse to borrowing moneys for the purpose of carrying on the Company's business. Some particulars of the loans are as follows: (1) In December, 1890, £8,500 was borrowed

from the Empire of India Corporation to pay part of the purchase-money to Woodhouse and Rawson, Limited. The sum actually received from the corporation was £7,960. (2) In April, 1891, £10,000 was borrowed from Mr John Wood, at 7 per cent. (3) In February and March, 1891, £20,000 was borrowed from Martin's Bank, at 6 per cent. interest and 5s. per cent. commission. (4) During April and May, 1891, the directors borrowed further sums from their bankers amounting to £11,000 at rates varying from 6 per cent. to 6½ per cent., and on July 2, 1891, £10,000 at 7 per cent.

"The following loans were contracted between July 31, 1891, the date of the balance sheet, and November 13, 1891, the date of the general meeting at which the accounts were presented and the dividends approved –viz : (1) On September 9, 1891, £25,000 from the Founders' Stock and Share Trust at 7½ per cent. ; (2) on October 23, 1891, £10,000 from Martin's Bank at 6 per cent.

"Since November, 1891, the directors have found it necessary to continue borrowing, in some cases at a very high rate of interest.

"The dividends paid for this year (to July 31, 1891) were the last that the Company has paid ; the dividend guarantee fund has therefore, notwithstanding all the representations regarding it, proved a very deficient protection to the shareholders."

The accounts for the year ending July 31, 1892, showed the utter rottenness of the whole concern. During the two preceding years 8 per cent. had been paid on the preference shares and 15 per cent on the ordinary shares The dividends, as will be seen by the remarks quoted, were hardly justified had the accounts been made up on a better business footing. The third balance acknowledges special losses amounting to £69,531, and the net loss for the year amounted to £129,764. 11s. 5d.

We should have liked to have given this damaging document in full, but must forbear. The statement of affairs, according to the official receiver, was very much delayed, and no adequate reason has, in his opinion, been assigned for this delay. The summary of the statement of affairs shows that the gross liabilities are over £212,000, and the assets are so estimated as to show 20s. in the pound on this amount, with a total deficiency as regards contributaries of £448,321. 7s. 11d. ; in other words, this managing director, or directorate, in the course of a little more than a couple of years has by some means or other –it can hardly be called business operations—got rid of that large amount.

THE DEVELOPMENT AND TRANSMISSION OF POWER FROM CENTRAL STATIONS.*

BY PROF. W. CAWTHORNE UNWIN, F.R.S.

LECTURE VI.

(Concluded from page 569.)

When the Niagara Commission met in London, two years ago, there was, the author believes, only a single installation in Europe where power was developed and distributed electrically for motive-power purposes to many consumers. That was the interesting work carried out by Messrs. Cuenod, Sautter, and Co., of Geneva, at Oyonax, in France Turbines of about 250 h.p., at Charmines, generated a continuous current at 1,800 volts, which was transmitted eight kilometres by overhead wires to Oyonax There the current was reduced by motor transformers and distributed, partly for lighting, partly for driving motors in a number of small workshops. Nothing could appear more prosperous than this village when the author saw it in 1892. But at that time only about 30 h.p. was distributed for motive-power purposes, and about 40 h.p. for electric lighting. About that time the Schaffhausen installation began working, which was described fully by Mr Gisbert Kapp. That plant was delivering last year about 500 h.p. to one spinning mill. Probably now the power is more widely distributed A very interesting transmission was erected by M Hillairet, at Domene, near Grenoble. A turbine of 300 h.p. drives a dynamo at 240 revolutions per minute. This transmits a current at 2,850 volts by an overhead line a distance five kilometres to a paper mill In the mill is a motor of 200 h.p. running at 300 revolutions. The total efficiency of dynamo, line and motor is 65 per cent.

All the three installations just described have three features in common. The electric current is a continuous current, it is conveyed by an overhead wire, and the source of energy is water power.

Very probably, in future, alternating currents will replace continuous currents for distant transmissions. It has been decided to use alternating currents, simple or of two phases, for the transmission from Niagara to Buffalo. Alternating current dynamos are free from some of the insulation difficulties which have to be encountered in continuous-current machines, and can be worked probably at tensions impossible for continuous current machines. If motors for alternating currents can be made simple and self-starting, like continuous current motors, then the facility of transforming the voltage of the current in a purely statical transformer is an advantage which will give alternating currents a superiority in long distance transmissions. But here again the cost of transformers is a not unimportant factor in determining the feasibility of a transmission. Probably it is only where water power is available, and in most cases only where cheap overhead transmission is possible, that electricity can be supplied at a cost permitting it to compete with other sources of power.

Electric Distributing Mains.—In all distributions of electricity for power purposes to a distance hitherto carried out, except some mining installations, bare conductors carried on wooden telegraph posts have been used In cases like that at Oyonax, where the line is carried over fields to a small village, such a cheap method may be used without much objection, even when high tension currents are transmitted In that case, however, there is a liability to injury, especially to injury from frost and from lightning, which must be reckoned with. It is fair to point out that when the cheapness of electrical transmission is put forward as a reason for adopting it in preference to other methods of transmission, it is almost always assumed that such rough and cheap expedients as an overhead conductor on telegraph posts can be adopted. To a mechanical engineer such arrangements do not appear to afford adequate security or permanence for an important power distribution. In proportion as the number of consumers taking power from a common source becomes greater, the inconvenience and damage resulting from any stoppage of the supply of power becomes more serious Hence it will probably prove to be necessary, if any general system of power distribution by electricity is carried out, to place the conductors in subways where they are protected from injury Such a construction, however, will necessarily increase the cost of electrical transmission

The smallest self respecting town requiring a water supply would not hesitate to build such a concrete conduit as that shown in Fig. 31. D'Arcy built such a conduit 13 kilometres in length for

FIG. 31.

the water supply to Dijon. It is the smallest conduit accessible throughout. An important electrical power distribution needs permanent and secure construction as much as a system of water supply. An objection is sometimes made to a subway for bare conductors carrying high tension curents that there would be danger to life in traversing the conduit. To obviate danger as far as possible, the conductors have been placed in recesses. Further, by movable metal screens put in connection with a return or earthed conductor, any part of the conduit could be made absolutely safe while repairs or alterations were in progress. The figure shows, of course, only a sketch of a possible arrangement, but some permanent protection for conductors will have to be adopted in important electrical distributions.

The Herstal Installation.—In 1886, the manufacturers of small-arms in Belgium formed a syndicate. To carry out a large order, the society decided on the erection of new workshops with tools of the most modern construction. M Leon Castermans has given an account in the *Revue Universelle des Mines* of the development of the plans of the works and of the reasons which led to the adoption of electrical transmission.*

The operations to be carried on involved the construction of a number of different factories more or less distant, and so arranged as to be capable of future extension. In these factories it was found necessary to arrange for 13 lines of shafting carrying a total

* Howard Lectures delivered before the Society of Arts.

* *Revue Universelle des Mines*, xix. 1892.

of 200 effective horse-power, or allowing for loss in transmission and engine friction, 300 i.h.p. Electric lighting was next decided on, and for this an additional 100 i.h.p. was required.

It now became a question of driving the different lines of shafting from the steam engine, and for this some system of transmission had to be selected. The mechanism between the steam engine and the lines of shafting and belting in the workshops, from which the tools are directly driven, may be termed the intermediate transmission. The arrangements of this transmission are required to subdivide and distribute the motive power, and to effect such modifications of velocity as are necessary. In this intermediate system a gradual subdivision of power must be carried out, involving, if ordinary mechanism is employed, a waste of power at each step of the process. The aggregate of these losses is large. It is a special inconvenience of any mechanical system of transmission that no part can be disengaged from the transmission without the use of more or less costly and cumbrous appliances, and hence, practically, when all the machines are not running, a good deal of the transmission is kept running uselessly. Hence, the waste of work which the transmission occasions when running at full load, is largely increased when only a part of the tools require to be driven.

Two systems of intermediate transmission were first studied—a system of shafting, gearing, and belts, and a system of rope transmission. It was found that the moving part only of the intermediate transmission would weigh 40 tons besides 30 tons of pedestals and other supports. Practically, the whole of this would be constantly running, occasioning frictional loss and requiring attention and lubrication, whether much or little work was done.

There is a further inconvenience of such systems indicated by M. Castermans. They do not easily lend themselves to extensions of the works. Either they must be made of excessive size at first, or, when an extension is necessary, they must be removed and replaced by a new transmission.

The study of the waste in ordinary systems of transmissions to such a group of workshops, led to the consideration whether the mechanical intermediate transmission could be replaced by electric transmission, with separate motors to each principal line of workshop shafting.

It was estimated that 260 effective horse power were required on the 13 lines of shafting. To cover contingencies, motors of an aggregate of 200 h.p. were selected, and, allowing for the loss in these motors, it was estimated that 297 h.p. of electrical energy would have to be transmitted to them. That required a dynamo taking 336 h.p. at the crankshaft of the engine, or 360 i.h.p. The effective work on the driving shaft of the machines is therefore 72¼ per cent. of the indicated work of the engine at full load.

The electric system, then, has these advantages: (1) Simplicity in the transmission between the engine and secondary motors by conductors instead of by shafting and gearing; (2) saving of loss in running an intermediate system of transmission constantly, whether much or little work was being done; (3) greatest efficiency of transmission, even with full load; (4) facility for effecting future extensions with the smallest modification of existing plant.

The system has been carried out very successfully. A steam-engine of 500 h.p., built by Van den Kerchove, running at 66 revolutions per minute, drives the armature of a single dynamo keyed on its crankshaft. This armature serves as the flywheel of the engine. There are two commutators each taking half the current. The maximum current is 2,440 amperes at 125 volts.

The secondary motors, which drive each a line of shafting, are two-pole motors, with Gramme ring armatures and carbon brushes.

The Herstal plant has been entirely successful, and there is no doubt that the distribution of the motors, which saves a number of intermediate transmissions, must lead to economy of motive power. But it is fair to point out that this problem of distributing the motive power of large works did not first arise at Herstal, and can be solved with similar advantages in other ways. It has always been a question, where steam power is used, whether it is desirable to concentrate it in a single engine or to work with each principal line of shafting driven by a separate engine. In dockyards, distribution of power by pressure water or compressed air has long been practised from precisely the same motives as those which influenced the engineers at Herstal. In some large works gas engines, distributed at various parts of the works, are being adopted to replace the single steam engine and complex intermediate transmissions previously in use. At Seraing, for 20 years there has been a distribution of power by compressed air, working motors on individual machines. At Birmingham, in several factories, air motors, involving as little trouble as electric motors, were used to drive small divisions of the machinery, and a large amount of shafting previously in use was removed.

Electric Transmission for Mining Work in Nevada.—An interesting case of the transmission of power electrically is that at the Comstock Mines, Nevada. There existed at the mines a 10ft. Pelton wheel driven by water supplied under a head of 460ft. and furnishing 200 h.p. To obtain additional power the water from this wheel is conducted by two iron pipes down the vertical shaft and incline of the Chollar mine to the Sutro tunnel level. It is there delivered at a pressure of 680lb. per square inch, equivalent to 1,630ft. of head, to six 40in. Pelton wheels. The jet to each wheel is only ⅝in. in diameter, and each wheel developes 125 h.p. at 900 revolutions per minute. Each Pelton wheel is coupled to a Brush dynamo, generating current, which is led to the surface, where it drives by dynamo motors a 60-stamp mill. The Brush motors revolve at 850 revolutions per minute. Of 700 h.p. developed by the Pelton wheels, 435 h.p., or 60 per cent., is said to be delivered at the motors. The Pelton wheels weigh only 1·8lb. per electric horse-power.

The Genoa Installation.—Exceptional circumstances have made it possible at Genoa to establish an electric supply in connection with a water supply. Some 10 or 12 years ago works for supplying water to Genoa, additional to others then in operation, were constructed. The water is obtained from streams on the Piedmont Liguria frontier, and two large impounding reservoirs have been constructed on the Gorzente River, an effluent of the Po. The reservoirs are 2,050ft. above Genoa, there being a large surplus fall not required as head for the water supply. To relieve the pipes of unnecessary pressure, three relieving or service reservoirs were constructed, reducing to about 600ft. the pressure available for the transmission of the water to Genoa. The first reservoir is near the outlet of a tunnel by which the water is carried through a mountain ridge, and is 360ft. below the tunnel. At that point 730 gross horse power are utilisable. The second reservoir is 360ft. below the first, and there also 730 gross horse power can be obtained. The third reservoir is 500ft. below the second, and there 1,000 gross horse power can be obtained. The water supply scheme has not been entirely successful, and the engineer, M. Bruno, and the consulting engineer, M. Prove, were led to consider the utilisation of the surplus fall to generate electricity, to be transmitted for lighting and power purposes to Genoa, distant about 16 miles.

At the three points described, electric generating stations, named after the Italian electricians, Galvani, Volta, and Pacinotti, are now in operation.

A first installation of a turbine of 140 h.p. was made in 1889, at the Galvani station. This proved successful, and the further development of the stations was undertaken. The Volta station supplies electricity to 15 motors distributed along the valley from Isoverde to Genoa, and to a motor of 60 h.p. at the railway station in Genoa. It also supplies motor transformers at the central electric lighting station in Genoa. The remainder of the power at this station, amounting to 600 h.p., is utilised by means of telodynamic transmission. The Volta station supplies electricity for lighting the station of Sampierdarena by a motor of 60 h.p., driving 12 Siemens and two Technomasio dynamos, and also supplies electricity for motive power to a number of mills and factories and the repairing shops of the railway. Messrs. Cuenod, Sautter, and Co., of Geneva, who constructed the electrical plant, have furnished the following details. Messrs. Rieter Bros., of Winterthur, constructed the first turbines erected. The remainder have been constructed by Messrs. Faesch and Piccard, of Geneva.

Electrical System.—The distribution is in series at constant current. The generating dynamos maintain a current of constant intensity in a single circuit which traverses all the motors. They supply a constant number of amperes whatever the number of motors at work. The voltage is essentially variable. At certain hours all the motors are out of action. Then the dynamos furnish a current at 450 or 500 volts corresponding to the loss in the circuit. At certain hours both the motors supplying power and the motors driving dynamos for lighting are in action. Then the voltage reaches 5,000 to 6,000 volts.

Galvani Station.—This has a single group of machines, consisting of two Thury continuous-current dynamos, coupled by Raffard couplings to a Rieter turbine of 140 h.p., having a normal speed of 450 revolutions per minute. In addition, a jute factory absorbs the power of two Rieter turbines of 300 h.p., the power being transmitted to it by telo-dynamic cables. The generators have six poles, and give at full load 47 amperes at 1,000 to 1,100 volts. Their speed varies from 20 to 475 revolutions per minute according to the demand for power. The dynamos are coupled in series, and work day and night.

Volta Station.—This has been in operation since 1891. There are four turbines of 140 h.p. each, and eight dynamos working at 47 amperes and 1,000 volts at full load. These generators work at constant speed, and the regulation is effected by varying the exciting current. The regulation is effected by a single regulator, however, many generators are in action. The main turbines are Faesch and Piccard turbines with relay governors, which maintain a strictly constant speed.

The regulation of the exciting current involves difficulties, because the voltage of the main circuit must vary from moment to moment, and sometimes quite suddenly, when motors driven by the current are thrown out of action. The motors are thrown out instantly by short-circuiting them. To meet these conditions, the exciting dynamo is driven by a separate 15 h.p. turbine, which has as little inertia as possible. The exciting dynamo has a very light armature, so that it follows instantly the variations of speed of the turbine driving it. The exciting dynamo is itself excited by a small machine serving to light the station, and the stability of its magnetic field is thus independently secured. The turbine driving the exciting machine is provided with a relay governor, but the conical pendulum, ordinarily used to secure constant speed, is replaced by a solenoid holding in equilibrium a soft iron core weighing 33lb., which is directly attached to the valve of the relay. A leather belt keeps this core and the valve in rotation, so as to practically annul any frictional effect. A spring and counterweight permit the adjustment of the action of the regulator. The solenoid is traversed by the current in the main circuit, which is normally 47 amperes. If the current augments, the core of the solenoid rises, puts in action the relay, and closes the sluices of the turbine driving the exciter. *Vice versa* if the current decreases, the relay opens the turbine sluices.

The system Messrs. Cuenod and Sautter state has given good results. Nevertheless, at the third, or Pacinotti, station, a return has been made to the system adopted in the Galvani station. The regulation is effected by varying the speed of the main turbines, which are constructed with as little inertia as possible, and have no speed regulators.

The Transmitting Arrangements.—The current is transmitted by bare copper wires, ¼in. in diameter, carried overhead on poles, with porcelain and oil insulation. The greatest distance of transmission is 30 miles. The line has a resistance of about 500 volts, or an efficiency at full load of 90 per cent.

The Motors.—The motors are all Thury motors, and are from 5 h.p. to 60 h.p. From 5 h.p. to 18 h.p. they are bipolar. Their regulation is effected by shunting, more or less, of the current, and they are all placed in series. Larger motors are multipolar, and these are regulated by displacing, more or less, the points at which the current enters and leaves the motor. This has the effect of reducing the magnetic field by causing some of the convolutions to be traversed in a direction reverse to the normal. Each motor is governed by a relay, and has a flywheel. A lever and counterweight is provided to adjust the governor.

The ratio of the effective work at the motors to the effective work of the turbines is stated to be 72 per cent.

Transmission at Biberist, near Soleure.—Messrs. Cuenod, Sautter, and Co. have also carried out a power transmission between Ronchatel and Biberist. Turbines of 360 h.p. have been erected, and the power is transmitted 28 kilometres to a paper mill. The generating station has two Thury continuous-current dynamos coupled to the turbines by Raffard couplings, and running at 275 revolutions per minute. Each dynamo gives a current of 3,300 volts, and the two dynamos are coupled in series. The current is transmitted by a bare copper wire, ¼in. in diameter, on simple porcelain insulators. The receiving station has two dynamos similar to the generators, making 200 revolutions per minute, and driving directly by Raffard couplings the machinery of the mill. An efficiency of 70 per cent. is guaranteed.

The Lauffen-Heilbronn Transmission.—The single case known to the author of the use of alternating currents for motive power distribution is at Heilbronn. The owners of the Wurtemburg Cement Works at Lauffen on Neckar, having surplus water power, conceived, in 1879, the idea of utilising it to supply electricity in Heilbronn, some six miles distant. They accepted plans for using the three-phase current. The Lauffen generating dynamo runs at 4,000 amperes and 50 volts. The voltage is changed to 5,000 by a transformer for transmission to Heilbron, and then reduced to 1,500 for distribution. Part of the current is further reduced to 100 volts in a network for lighting. The charge for current for lighting is 9d. per kilowatt hour. Current used for motors for industrial purposes is charged at 4d. per kilowatt hour, or about £42 per effective horse-power year of 3,000 working hours. This is for current alone, exclusive of interest on the cost of motors. In November last there were on the system 11 motors aggregating 32 h.p., a rather insignificant motive power distribution. So far as the author has had opportunity of judging, the three-phase system with double transformation is an expensive method of distribution. It is worth noting that Mr. C. E. L. Brown, who designed the Lauffen dynamo, speaks doubtfully as to the system. He says that one object of the Lauffen-Frankfort experiment was to show the advantages of the three-phase system for power distribution. But that it actually showed the disadvantages of the system—viz., complication in line, generator, and transformers.

INSTITUTION OF ELECTRICAL ENGINEERS.

DISCUSSION ON PROF. FORBES'S PAPER.

(Concluded from page 565.)

Mr. Alex Siemens thought it only right to the commission that asked for tenders that he should explain the conditions under which they were invited. Perhaps Mr. Ferranti, who had complained about the policy pursued, did not know what those conditions were. When he (the speaker) had the pleasure of speaking with the president of the commission the latter mentioned to him that the various competitors were to hand in competitive designs, and that the commission was to supervise the construction of the machines in America. His firm competed, but did not send in any detailed designs, and in consequence they were excluded from the prizes. Anyone who had read the conditions could see from the beginning that the intention was to construct the whole of the machinery in America. He agreed with Mr. Ferranti that the prizes of £200 to £500 were inadequate. No question ought to arise about sending the current along cables at 20,000 volts. His firm had used a concentric cable which had carried 24,000 volts, and since then it had been used in experiments with current at 50,000 volts, and occasionally up to 60,000 volts, and there had never been anything wrong with it. They had found that the continuous current was the best for the purpose, and he was not sure that the Cataract Construction Company would not ultimately be converted to the use of the continuous current.

Mr. S. Evershed submitted in connection with the subway that a point of great importance would be the induction between the conductors, whether solid or laminated. Another point was that of coupling the machines in parallel. He desired to know the utility of an artificial load when coupling in parallel. He had never seen such an arrangement in England, and he wanted to be informed as to what advantage Prof. Forbes regarded as obtainable by using an artificial load in exciting machines in parallel.

Mr. R. E. Crompton said there had been an important omission. As far as the interest of the paper was concerned, it was like "Hamlet" with a part left out. If the paper was anything, it was a first attempt to describe a large commercial undertaking of transmission of power. The whole question was one of £. s. d.: what would be the cost of power at Buffalo, and how would it compete with the cost of steam power in that town. There was nothing in the paper which gave them any information on this head. The questions of the E.M.F. to be employed, whether continuous or alternating current, periodicity, etc., were, no doubt, of great importance, but they were subsidiary to the question of what could be done with a given capital, what the cost of the energy would be, and what the interest on the money spent would be. That was a factor about which they must know something before discussing the scheme. He, in common with many other engineers, had considered similar though smaller schemes, but they had been obliged to abandon them, as the interest and the cost of the plant were so great as to overwhelm the advantages of using water power. The barefaced attempt to pick the brains of the world, and then utilise it for the benefit of the manufacturers, was a thing to be admired! He was sorry to say it was even carried out in this country. He spoke feelingly. The Americans had only done on a large scale what so many around them in this country were doing. Theoretically, continuous currents were the best for the job. The recent explosion in the French Chamber would be very small as compared with that of an arc starting in the subway, and which, as Mr. Ferranti had remarked, would go to the other end. He wondered whether Prof. Forbes had made any experiments as to the insulating power of porcelain. Very great failures had taken place where the overhead material had been used for underground work. The result had been that they had made great improvements, and had now got material which carried 200 volts. If material could be obtained to carry 20,000 volts that was beyond his comprehension. Oil insulators were supposed to be of utility, but after a time they proved to be entirely useless. He did not agree with Mr. Ferranti that 42 periods were sufficient for electric lighting. He had seen many of the Ganz stations working at 42 periods, and the arc lighting was disgraceful, and when Messrs. Ganz and Co. were in competition with any other company they lost the arc lighting work.

Mr. Mavor, who had during the past year been carrying out work in connection with culverts, observed that it would have been interesting if the author had mentioned how the subway was to be ventilated. The question of the variations of the atmospheric conditions must be very difficult. He considered that the method of drainage was insufficiently described.

Major-General Webber said they ought to remember that the author had brought before them a paper referring to work that had not yet been carried out, and that modifications would have to be made in carrying out the work. They ought not to forget that Prof. Forbes had given credit to those who had given him advice. Very few consulting engineers would have ventured to give them a description of works that had only been designed.

Mr. C. E. L. Brown (whose remarks contained in a letter were read by Mr. Kapp) said that he had come to the conclusion that a higher frequency than that adopted by Prof. Forbes would have been better. It was astonishing that so much was still said of the difficulty of running alternators, single or multiple, in parallel. He had run machines in parallel under the most difficult conditions, and had never found the slightest difficulty. He had come to the conclusion that the coupling of alternators in parallel was as easy, if not easier, than that of direct-current machines. Mr. Brown had never found an artificial load necessary. With regard to the transformers, there was no doubt that a high frequency was best. He pointed out that it was far more difficult to design a large transformer to run cool than a small one. Dealing with the question of motors, they could be constructed of suitable design to give as good results with high frequency as with low. In connection with incandescent lighting, it was advisable to be well above 30 periods, and for arc lighting not less than 40. Single-phase motors were now on the market. Considering the number of designs sent in, it was surprising that Prof. Forbes should have decided upon the worst arrangement possible for his machines.

Prof. Forbes, in reply, said that the discussion had hardly maintained the position of the Institution and of the capability of its members to discuss a large and important problem. He attributed this to their not having had sufficient time to study the question in all its bearings. With regard to low frequency, he was astonished that men like Mr. Mordey, Mr. Kapp, and Mr. Swinburne were incapable of realising its benefits, and he felt sure that they would be converted to his views on further thought, just as the International Commission was with respect to alternating currents. He regretted that certain accusations had been made against the Cataract Construction Company and its international commission, but the scheme which had been accepted was his own, and he was perfectly satisfied with the loyal manner in which the Cataract Construction Company had carried out their obligations. In 1890 he had given them a report with detailed drawings and estimates, urging the use of the alternating current—that it should be generated in two phases; that 2,000 volts was to be used for the local work, and transformers to raise the pressure for transmission to Buffalo; that the motors were to be synchronising motors, Tesla two-phase motors, and motors with laminated fields and commutators. The only mistake made in that report came from a desire to use machinery then on the market, for which reason Mordey alternators were recommended. They knew now that their high frequency, and other features, rendered them unsuitable. Dr. Fleming's remarks were a redeeming feature in the discussion. He had realised thoroughly that "the advantage of adopting a low frequency and low capacity is something enormous," and that "there can be no doubt about the wisdom of the choice of selecting this low frequency for a case such as the Niagara transmission." Prof. Forbes considered that this, coming from a man who had the [illegible] experience [illegible] as a warning, must be looked on as a statement carrying the greatest

weight. Mr. Mordey and others who spoke about the lighting as being an important feature, had evidently no idea of the character of the work; and Mr Mordey's criticisms with regard to small lighting transformers had no bearing on the large transformers required for Niagara Falls, where there was no difficulty in getting much higher efficiencies than those quoted by Mr. Mordey. With regard to parallel working, Mr Mordey had said: "If 100 periods succeeds, why go to 25 periods?" He (Prof. Forbes) considered that this gave the idea that Mr Mordey's high frequency alternators worked perfectly in parallel He claimed that they did not, and quoted experiments, made with Mr Mordey, to prove this He also alluded to the breakdowns which Mr. Mordey had had in parallel working, and said that the Cataract Construction Company could not afford to have such experiences; and it was for the same reason that he wished to use an artificial load, so as to introduce every safeguard that could be devised especially as they were found necessary for efficient parallel working at Tivoli Mr Mordey thought that the Hughes effect would not be sensible but he had not realised what large masses of copper were required for carrying the huge power to be dealt with. Both Mr Mordey and Mr Kapp placed motors in the list of things that did not support the reduction of frequency, but they had given no evidence, whereas he had given experimental proof and theoretical explanations to the contrary. Mr Mordey's proposals to use 500 volts in the dynamo was utterly unpractical, as the transmission of 50,000 h p would require 400 square inches of copper Mr Kapp had made an erroneous estimate of the copper required in different systems He (Prof. Forbes had had occasion to correct the erroneous argument as laid down by Prof Elihu Thomson, and he would publish the refutation with his reply. At the end of the paper a proof had been given that, in doubling the frequency of a polyphase motor, the losses in the field were increased 42 per cent Mr Kapp, while admitting the 42 per cent., claimed that the motor at higher frequency was giving 2½ times as much power He (Prof Forbes) referred to the drawings, and showed that in both cases the total number of lines of force was the same and cut the wires of the armature at the same speed, and therefore gave the same E M F. and current in the armature and the same power. If anyone but Mr. Kapp had raised these objections, he would have considered them beneath notice After pointing out errors in Mr. Kapp's view of the unsuitability of certain synchronising motors, he said he was pleased to find that Mr. Kapp approved so highly of the design which he had got out for the dynamos With regard to Mr. Ferranti's imputation that the Cataract Construction Company had got in designs from European manufacturers with the sole object of getting their ideas for nothing, he indignantly denied this, and assured the meeting that it would be impossible for him to act as consulting engineer to any company that did this With regard to Mr Ferranti's other imputation, that his (Prof. Forbes's design was borrowed from that of Mr Brown's he said there was more difference between his design and those of any of the manufacturers than between the designs of the manufacturers themselves, but Mr Ferranti's assertion was completely overthrown by the statement of Mr Brown's, just read, that his (Prof Forbes's design was the worst possible. With regard to Mr. Crompton's desire for a statement of the cost of producing a horse power, he had to say that, even when the works were completed, and the actual working cost made out, this was a piece of information that would not be likely to be given. After referring briefly to the remarks of some other speakers, he said that, while he regretted, for the sake of the reputation of some of the speakers, the remarks they had made without sufficiently considering the question, yet nearly every objection of one speaker had been answered by another. Not a single objection had been raised which he had not considered carefully while making his plans, and he felt a great deal fortified in all the conclusions he had arrived at by the character of the discussion, and he was more than ever certain of success in this great work.

PHYSICAL SOCIETY.

At a meeting of the Physical Society, held on the 8th instant, a paper by **Mr James Swinburne** on "**A Potentiometer for Alternating Currents**" was read by **Mr. Blakesley**. After referring to the many advantages of the "potentiometer method" of measurement, the author describes an arrangement by which alternating pressures can be measured. A quadrant electrometer with a double fishtail shaped needle suspended by a torsionless fibre is employed. The electrostatic attraction exerted by an alternating pressure between the needle and one pair of quadrants is balanced by the force due to a steady pressure between the needle and the other pair of quadrants. The magnitude of the steady pressure is determined by a potentiometer and standard cell, and the effective value of the alternating pressure thus deduced For measuring alternating currents a differential electrodynamometer, having two fixed coils and one moving coil and no controlling spring, is used. A direct current, measured by the fall of potential over a small resistance, is passed through one of the fixed coils, the alternating current through the other fixed coil, and the moving coil is included in both alternating and direct current circuits. When the two forces balance the currents are taken as equal. Several small inaccuracies to which the method is subject are mentioned in the paper. **Prof S. P. Thompson** enquired if the fishtail shaped needle of the electrometer was novel. **Mr. Blakesley** said the author had mentioned the needle previously. He (Mr. Blakesley) thought the name "potentiometer" was not very suitable. In effect, the so-called measurement of *pressures was a comparison of two powers.*

COMPANIES' MEETINGS.

SWAN UNITED ELECTRIC LIGHT COMPANY, LIMITED.

Directors J S. Forbes, Esq., chairman; W. Cuthbert Quilter, Esq., M.P., deputy chairman; E W. Batt, Esq, Major S. Flood Page, J. W Swan, Esq

Eleventh annual report of the Directors and statement of accounts for the year ending September 30 1893, presented at the ordinary general meeting of the Company, held at the Westminster Palace Hotel, Victoria street, S W, on Wednesday last.

The profit and loss account for the year shows a credit balance of £28,877 9s 6d., which, together with £6,824 17s. 9d brought forward from the last account, leaves disposable the sum of £35,702. 7s 3d. An interim dividend in respect to the first half of the year amounting to £9,376. 15s. 9d has already been paid The Board proposes that a further sum of £18,012 19s be divided, free of income tax, and that £8,312 12s. 6d be carried forward. The distribution of this amount in accordance with Clause 77 of the articles of association works out at 3s. 6d. per share on the 78,949 ordinary shares of the Company, £3 10s paid, and at 4s. 3d per share on the 19 750 £5 fully paid, being equivalent to 7½ per cent. per annum on the partly paid, and of rather less than 7½ per cent. upon the fully paid, shares The warrants will be issued on the 23rd December to the shareholders standing upon the register upon the 12th December instant. The shareholders may be reminded that Messrs Quilter and Swan were deputed to meet Sir John Lubbock and the Earl of Lichfield, acting for the Edison and Swan Company, with a view of suggesting a basis on which an amalgamation with this Company could be effected. This basis having been generally agreed upon, it became necessary to ascertain in the first instance whether the fully paid up shareholders of this Company are prepared to accept the terms Messrs Quilter and Swan have now by circular addressed each fully paid shareholder with a view of ascertaining whether they approve of the amalgamation of the companies on the arranged basis. As soon as this has been ascertained, the matter will be brought before the partly paid shareholders, and, if approved, a general meeting will be called to give effect thereto. The directors who retire by rotation are Mr W Cuthbert Quilter, M P., and Major Flood Page, who, being eligible, will offer themselves for re election. Messrs Welton, Jones, and Co, the auditors, will also retire, and will offer themselves for re election

The eleventh ordinary general meeting of the Company took place on Wednesday at the Westminster Palace Hotel, S.W., Mr. J. S. Forbes presiding.

The **Chairman**, in moving the adoption of the report and accounts which are given herewith, apologised for the meeting being called at a later date than last year, but said he thought the reason would be regarded as satisfactory when he explained it. The Directors promised at the last meeting that measures should be taken with a view of combining the remnant of their business with the bulk of their investments in the Edison and Swan. The running out of the patents and the altered condition of things likely to arise when they were out of the influence of protection and in open and free dealings, no doubt made it desirable that their affairs should be as compact as possible, and managed as economically as possible. During the interval negotiations proceeded between the two companies, the Edison and Swan and the Swan, and had now reached that stage when, as far as the Directors were concerned, their responsibility would end, and that of the proprietors would begin. Briefly, what was the price which the Edison and Swan were to pay to the Swan shareholders for the remnant of their business not already included in the Edison and Swan? The Directors thought the better plan was that two gentlemen interested in the Swan Company and two interested in the Edison and Swan Company should have the necessary preliminary discussions and should if possible arrive at some basis of agreement, and that had been done. The matter was a good deal complicated by the relative position of the fully paid shareholders and the partly paid shareholders in the Swan Company. The Directors, therefore, begged Mr. Swan, who represented, for the most part, a holding in fully-paid shares, and Mr. Quilter, who represented more especially the partly paid shares, to put their horses together and to see what would be a fair method of dealing with the cake when they had it to cut. Of course, it had to be ascertained how big the cake was, the ingredients of which it was composed, and whether it would be palatable. That involved another process. Sir John Lubbock, although not a director of the Edison and Swan Company, was originally intimately connected with it, and was good enough, in conjunction with the Earl of Lichfield (a director), to consider the question from the point of view of purchasers. After rather prolonged negotiations, a basis had been arrived at, not only as to what the Edison and Swan was prepared to give for the residuum but as to how the purchase price was to be divided between the fully paid shareholders and the partly paid shareholders. The scheme was rather complicated, and it was not so easy to arrive at a conclusion, but the agreement arrived at seemed to be as equitable as was possible in a case where the factors were partly existing and partly problematical. Briefly, it was this. The Edison and Swan Company, in which they were interested to the extent of 60 per cent., agreed to give £100,000 in the shape of 4½ per cent. debenture stock, which, of course, would form a first charge over its whole income. The shareholders in the Swan Company would by that process put over their own heads £60,000 of 4½ per cent. debenture stock; their partners in the Edison and Swan would put £40,000. Dealing with the bargain, it was to be remembered that £100,000 debentures of the first charge was extremely safeguarded compared with the rest of the capital, because a debenture was a mortgage on the property, and the interest was cumulative. Assuming as they were obliged to assume the worst in such cases and assuming nothing to arise which would raise an issue as between the two classes of capital, it was quite clear that the one had a great advantage in respect of its priority, both for principal and interest, over the other. That consideration must not be disregarded in weighing the quantity. He himself had purposely abstained from entering too fully into the discussion until it was concluded, because a man could not be buyer and seller too, and as he would have to present this matter to the shareholders of both companies, if it was agreed to, it was absolutely necessary that he should keep out of the discussions, and, when the result was arrived at, examine it as nearly as he could from the point of view of an impartial judge. He had examined it, and, being conversant with the difficulties of dealing with the positive factor in conjunction with a factor more or less uncertain, he had arrived at a conclusion that it would be a very good bargain for both sides. First of all, it would put the two things under one umbrella; secondly, it would strengthen their hands as against the severe competition to which they were probably about to be subjected, both in England and abroad. It would also effect certain economies which would be extremely advantageous to the united body. With regard to the profit and loss account, the proportion of further dividends accruing to September 30, 1893, on the Edison and Swan United shares, estimated at £6,000, was brought in because the theory of the amalgamation was that the Company, with its liabilities and income, would be merged as from October 1 into the accounts of the Edison and Swan Company. Treating this as a winding up balance sheet, it was essential to bring that £6,000 into the account in order that there might be no mistake when the fusion took place. With regard to the dividends received and due on the shares in the National Telephone Company, there was a considerable amount of money invested in Consols paying a miserable rate of interest, and the Directors thought it wise, when the price of those Consols reached a figure at which they could be sold without loss, to get out, and put the money into some undertaking which would pay some reasonable dividend. An opportunity offered at that time to take shares which were about to be issued by the National Telephone Company, and, as Mr. Quilter and himself both knew something of the position of that company, they persuaded their colleagues to put the money into it as an investment which would return a reasonable dividend. On that £25,000 they had received 5 per cent., instead of 2¾ per cent. Referring to the law costs, the Chairman said that, unfortunately, ever since the initiation of the lamp business they had been more or less in litigation, and, as the solicitors did not send in their accounts to date, there was always a running account. The Edison and Swan and the Swan Companies in much of this litigation were partners, and it had only been recently by the submission of a final account on the part of the solicitors of those law costs, extending over several years, both in this country and in Germany, that it had been possible to state the account properly as between the two companies. The agreeable position in which the Swan Company found itself was this, that in the aggregate sums paid by the two companies the Swan had been debited with £2,300 more than was fairly attributable to it, but it had now got it back, and the account was clear. With regard to the stock, of which they must always have a large amount on hand, the £8,507 shown in the balance-sheet only represented the stock in Germany, to which their business was now exclusively confined by the agreement with the French company. In Great Britain the stock was much larger. It was a satisfactory result that they had been enabled during the year to September 30 to work that stock down from £14,654 to £8,507, and that had been done partly by disposing of it, and partly by writing down the value of it in the books as carried over. He thought the account was now in a most wholesome state. During the last few years the Edison and Swan Company paid on the face of the accounts very large dividends, but those dividends were made up of two elements: the 7 per cent. to which the "A" shareholders were entitled out of the profits of the particular year, and payment in respect to that 7 per cent. during the years when it was not earned. Last year, for the first time, they were enabled to wipe out the balance standing to the debit of that arrear, and to carry over a considerable sum of money which had to be distributed between the Edison and Swan "A" shareholders and the "B." But the dividend under those circumstances distributed was 10 per cent., and, in comparison with the dividend in the present year, showed £12,000 less than the money carried over in 1892, when the item of unredeemed arrears was so considerably greater. The share capital was exactly the same as last time, and they had been able to bring their business down to such a condition as to approach the almost perfect state in the accounts. Last year sundry creditors amounted to £5,000; but it was now reduced to £3,000, and, looking at the nature of the business, that was a small sum. That left £35,702 available. For the six months ended March, 1893, they paid an interim dividend amounting to £9,376, and it was now proposed to pay enough to bring up the dividend to 7½ per cent. That would absorb £18,012, leaving £8,312 to be carried forward. The sundry debtors amounted to £33,772, which was very satisfactory when the item sundry creditors was looked at, and which showed a surplus of debtors, all good, over creditors of £30,000. That was explained by the fact that the Company could not afford to let its money lie idle and was obliged to invest it. £20,000 were invested on Stock Exchange loans, that was from fortnight to fortnight, of course, taking care that the security in respect to the advance was lodged, and the responsibility of the broker with whom the Company dealt was guaranteed. They had lent £10,000 to the Edison Company, so that the £30,000 was mopped up. The National Telephone shares were now worth a good deal more than the present premium. They had got rid of £29,000 of Consols and £5,000 of Prussian Consols, the latter being sold at a profit and the others at about their value.

Mr. Cuthbert Quilter, M.P., seconded the motion.

The **Chairman**, in reply to questions, said that supposing the agreement were carried out, the whole of the £375,000 capital of the Swan Company would disappear, and the capital of the United Company would stand at £350,000 plus £100,000. On the expiration of the agreement with the French company, at the end of next year, the restriction as to selling lamps would be removed. He thought it was quite on the cards that the Company would see it to be to its interest to be free of that restriction, and to be able to compete all over Europe. The Edison and Swan Company was not free to export lamps from Great Britain. The lamp patents now were absolutely gone, and therefore it came to this, that they would have for £450,000 the business of all Europe for what it was worth, because, being together, the bar of exportation from England would be removed, and they would be able to make lamps for the whole world, China included. They had tried to turn out the most efficient article, and during the years of protection they had had a monopoly of all the scientific information. Their factory was the best in the world, and their operations had not been confined to lampmaking. The Directors knew quite well the quality of every lamp produced, because they had bought them and tested them. He had not yet discovered that lamps could be made more cheaply in Germany than in England. The Company

had been playing off its factory in Germany against its factory in London, and they found that the result in London was rather more satisfactory than it was in Germany, because it turned out quantity. The Company was allowed to sell Edison lamps and Swan lamps, but the Edison lamp had disappeared. All the refuse stock in Germany had been bought up by speculators, and would, no doubt, be launched here as first-class German goods. When it came to goods of a first-class character, the Swan Company would be able to compete with all comers. They had some extremely valuable patents, having some years yet unexpired, in respect of fittings which for the lamps were almost indispensable and were now being made by hundreds of thousands. The Company had licensed many of the best firms in England, from whom they obtained a royalty.

Mr. F. W. Reynolds enquired whether the capital would be cut down, and also as to the £1 10s. liability on the shares.

The **Chairman** said that, in round numbers, they would be £60,000 less on paper than before. He did not see that either company was in immediate fear of new capital being required, and he might say that the competition, up to the present moment, had not in any way affected their sales. The Chairman then explained at length a circular which had been issued to the fully paid shareholders as to the reason and consequences of the amalgamation.

The report was adopted, and the retiring directors, Mr W. Cuthbert Quilter, M.P., and Major Flood Page were re-elected, and a resolution was passed authorising the distribution of dividends as mentioned in the report.

ELMORE'S FRENCH PATENT COPPER COMPANY.

A meeting was held on Wednesday at the Holborn Restaurant of the debenture holders and secured creditors of Elmore's French Patent Copper Depositing Company, to consider a scheme of arrangement between the Company and its creditors. Mr. C. J. Stewart, the official receiver and provisional liquidator, presided. It was explained that the object of the scheme was first to satisfy the claims of the debenture holders and creditors of the Company; and, secondly, to resuscitate the Company, so that the reversion of assets might belong to the shareholders. The **Official Receiver** having stated that he presided under an order from the Court, said he wished to make it very clear that he did not recommend the scheme in any form whatsoever. If it were adopted, those present must distinctly understand that it was not a scheme recommended by the official receiver. He did not say that the scheme was not the best one that they could adopt, but at the same time they must judge for themselves as to whether they would adopt it. The scheme was adopted with one dissentient.

In the afternoon a meeting of the unsecured creditors was held. **Mr. Stewart**, the official receiver, who again presided, explained that the debenture holders had accepted the proposed scheme, and it now rested with those present whether they would accept it. Practically, the scheme put an end to the liquidation proceedings. He did not, as official receiver, wish to hold out any inducement to them that they would be benefited in any way by the scheme. The scheme having been read and explained, the **Official Receiver** said the creditors were best able to judge from their former dealings with the Elmore Company whether the new company was likely to be the success which had been foreshadowed. On the motion of **Mr John Heal**, seconded by **Mr. Shurmer**, it was decided to approve the scheme, subject to the sanction of the Court.

The shareholders of the Company subsequently held a meeting at the Holborn Restaurant, under the chairmanship of the **Official Receiver**, who repeated the observations made at the earlier meetings, to the effect that he made no recommendation one way or the other with regard to the scheme. In reply to questions, he said the Court might decline the scheme, and anybody might be heard before the Court in opposition to it. It was, however, doubtful whether the Court would vary the scheme at all without a fresh meeting. After some discussion the meeting approved the scheme subject to the sanction of the Court.

BUSINESS NOTES.

Ashover.—The hydropathic establishment propose to adopt electric lighting.

Western Union Telegraph Company.—A quarterly dividend of 1¼ per cent. has been declared.

Fermoy.—Tenders are invited by the Town Commissioners for lighting the town by electricity.

Aberystwith.—The Town Council have decided to erect an electric lift up Constitution hill.

Western and Brazilian Telegraph Company.—The receipts for the week ended December 15 were £3,215.

Cherry Hinton.—The question as to the best method of lighting the streets is under the consideration of the parishioners.

West India and Panama Telegraph Company.—The receipts for the two weeks ended December 15 were £182 more than for the corresponding period.

Calcutta.—Messrs. Kilburn and Co., of Calcutta, have taken up an agency for Messrs. Crompton and Co., and also for Henley's Telegraph Works Company.

Leeds.—Tenders are invited for fixing the various fittings requisite in electric lighting inside and out Wren's Hotel, New *Briggate.* Applications to be sent to Mr. J. Townsend, at that *address.*

Melbourne.—The complete lighting of the city of Melbourne by electricity is likely to be accomplished by the beginning of the new year at a cost of £70,000.

Halifax.—The proposal to erect the central depot for the electric lighting on the vacant plot on the east side of the Halifax Parish Church is said to be meeting with much opposition.

Burton-on-Trent.—New schoolrooms connected with George-street Free Methodist Chapel have been opened. The hall, which seats 600 persons, and the principal rooms are to be lighted by electricity.

Universal Electric Lighting Company, Limited.—This Company has been registered with a capital of £5,000, in 10s. shares, to carry on business as electricians, electrical and mechanical engineers, etc.

Norwich.—The Town Council have decided to light the Council chamber and committee-room and the municipal offices and sanitary offices by electricity. The annual expenditure will amount to £150.

Loan Granted.—Treasury sanction has been received by the London County Council for the following loan, which is awaiting completion: Hampstead Vestry, £5,000 for electric light buildings and works, 30 years.

Telephonic Communication.—The district manager of the National Telephone Company states that the question of making Cleckheaton a joint exchange between Dewsbury and Bradford will not be lost sight of.

Falmouth.—Mr Grose is the pioneer of electric lighting in Falmouth, having just completed an installation of arc lights in the windows of his three shops, the interior of which are illuminated by 50 c.p. incandescent lights.

Barnsley.—Tenders are invited for lighting the Barnsley arcade and adjoining property by electricity, for the Barnsley Arcade Company, Limited. Applications are to be addressed to Messrs. Wade and Turner, 10, Pitt street, Barnsley.

Bristol.—The Town Council last week adopted the recommendation of the Electrical Lighting Committee, that they be authorised to apply to the Local Government Board for their sanction to the borrowing of a further sum of £24,000 for lighting purposes.

Nelson.—The Town Council have adopted the minutes of the Gas Committee recommending the acceptance of the tender of Messrs. Siemens Bros. and Co., Limited, at £1,031, for coupled engine and dynamo. The engine is of the Willans HH type.

Stirling.—The Town Council are to receive a report from Mr. Arnot, electrical engineer to the Glasgow Corporation, for the guidance of the Council in connection with the application of the Caledonian Electric Supply Company for a provisional order.

Cardiff.—A meeting of the Lighting and Electrical Committee was held on Tuesday at the Town Hall. Tenders were accepted for 250 lamp columns, lamps, and lampholders respectively. It was decided to erect about 40 additional lamps in various parts of the town.

Edinburgh.—The Town Council of Edinburgh have remitted to the Cleansing and Lighting Committee the question of considering and reporting on extensions in the electric lighting of various streets. Estimates for the first portion of the work will be invited in about a week.

Aluminium Company.—Mr Justice Wright had before him on Wednesday a petition by the Company for the reduction of its capital from £400,000 to £80,000, by reason of loss of capital. His Lordship directed the petition to stand over for further evidence as to the loss of capital sustained.

Harrogate.—Tenders are invited, by the 30th inst., for the supply of concentric insulated cables for high pressure distribution for the Corporation of Harrogate. Specifications may be obtained of Mr. S. Stead, borough surveyor, Municipal Offices, Harrogate, on payment of £1 1s.

Capital Required.—A private electrical company wishes to increase its capital to meet the needs of its growing business. The company could employ from £1,500 to £3,000. Communications to be addressed to the company's solicitors, Messrs. Cave and Co., 4, Fenchurch street, E.C.

Pilling.—A complete electric lighting plant, comprising oil-engine, dynamo, accumulators, and about 50 incandescent lamps, is being laid down at Fluke Hall by Mr. E. Dewhurst, electrical engineer, of Blackpool and Preston. It is rumoured that the church is to be lighted by electricity.

City and South London Railway.—The receipts of the Company for the week ending December 17 were £905, against £918 for the same period last year, or a decrease of £13. The total receipts for the second half year of 1893 show an increase of £143 over those for the corresponding period of 1892.

Dewsbury.—The Lighting and Water Committee reported on the 9th ult. that nine tenders had been received for building the central electric light station, and that the tender of Mr. Mark Scott, of Earlsheaton, for lighting station had been accepted. These minutes have been adopted by the Council.

Personal.—Mr. B. Holmes Jenkinson informs us, now that he has completed the work of electric lighting the Southampton Docks, he has been appointed to take charge of Messrs. Crompton and Co.'s lighting contracts for the Great Eastern Railway Company at Liverpool street, Bishopsgate, Shoreditch, etc.

Kingswood.—At a meeting of the Local Board, Mr. H. Anstey enquired what Messrs. Parfitt had to say in relation to the inferior lighting of the district. The surveyor was understood to reply that the current was at fault. The chairman enquired when the iron

posts were to come. In reply, the surveyor said he believed they were at Warmley Station.

Agents.—Messrs. Henry Rogers, Sons, and Co., of London and Birmingham, have been appointed sole agents for the United Kingdom of the Fonderie et Tréfilerie de Bronze Phosphoreux d'Anderlecht (Montefiore Phosphor Bronze Works), manufacturers of phosphor copper, phosphor bronze, and phosphor wire.

Plant for Sale.—The Blackpool Corporation have for sale their recent arc light plant, consisting of 10 Siemens dynamos, 6,000 c.p. arc lamps, semi-portable Robey engine and boiler, 16 nominal horse-power, old cables, etc. Particulars as to terms may be obtained from Mr. Wm. Chew, Princess-street Works, Blackpool.

Lighting at Taunton.—The report of the Electric Lighting Committee adopted by the Town Council last week, stated that in consequence of the arrest of Mr. Hunt the committee had appointed the assistant engineer, Mr. W. Cousens, as engineer in charge *pro tem.*, and that they had made such other arrangements for carrying on the works as they considered necessary.

Eastern Telegraph Company, Limited.—The directors announce the payment on January 15 of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum on the preference shares for the quarter ending December 31, and the usual interim dividend of 2s. 6d. per share on the ordinary shares, tax free, in respect of profits for the quarter ended September 30.

Huddersfield.—The Corporation invite, as will be seen from our advertisement columns, tenders for the wiring of and for the supply of electric light fittings for the model lodging house. Plans and specifications may be obtained upon application to Mr. A. B. Mountain, borough electrical engineer, St. Andrew's-road, Huddersfield. Sealed tenders to be sent to the borough electrical engineer not later than January 6.

Portsmouth.—Considerable progress is being made with the machinery for the supply of the electric light, and there is reason to expect that by the end of January the station will be complete. From a return just issued, the amount paid for purchase of land, erection of building, and other expenses up to October 16 last was £12,046, and the amount contracted, but not yet paid, is £36,650—in all £48,695. This will leave an available balance of £7,689 to provide for contingencies.

Yarmouth.—The Town Council have adopted a report of the Electric Lighting Committee. The committee stated the Mayor had been appointed chairman for the ensuing year; that the Board of Trade had approved the proposed method of lighting; and that the Local Government Board had sanctioned a loan of £15,000 for carrying out the scheme, and also approved of the site for the electric lighting station. Mr. Preece is to be instructed to prepare the specifications.

Liverpool Overhead Railway Company.—The directors have made a third call of £2 per share on 7,500 preference shares (first issue, Nos. 1 to 7,500 inclusive), payable at the Bank of Liverpool, Limited, Water-street, Liverpool, on Tuesday, January 9. The Board have also made a first call of £2 per share on 2,500 preference shares (second issue, Nos. 7,501 to 10,000 inclusive), payable on January 9. The traffic receipts of this railway for the week ending 17th inst. amounted to £634.

Bradford.—It has occurred to Mr. W. Glossop that, as the Bradford Corporation have succeeded in supplying electricity in the centre of the town in a most efficient manner, they might be induced to establish an installation in a district like Heaton if a sufficient number of the ratepayers could be found willing to use electricity in their houses instead of gas. For the purpose of testing the feeling of the Heaton ratepayers and obtaining information on the subject, he asks, in a circular issued to the ratepayers, that an accompanying form should be signed and returned to him.

Lighting at Wolverhampton.—As mentioned in our last issue, a report has been presented to the Town Council by the Lighting Committee with regard to the scheme for supplying the electric light. The committee were anxious that the installation of the electric light should be effected with the least possible delay, and among their recommendations was one that the tenders of the Electric Construction Company, Limited; Mr. John Thompson; the Epstein Electric Accumulator Company, Limited; and the Callender's Bitumen and Telegraph Works Company, Limited, should be accepted for the works included in the several specifications. The report, as stated last week, was adopted.

Monmouth.—At a meeting of the Town Council last week, Mr. Wilson referred to an article describing a system of electrical sanitation which was being experimentally tried at Havre. The Monmouth Corporation, he said, were in a specially suitable position for adopting such a system, if it could be proved effective, by the fact that they proposed working their sanitary and electric projects side by side. It seemed that they would be able in the course of time to put the sewage from the precipitation tanks right into the water at once. The point, therefore, suggested itself as to whether it was wise or not to saddle themselves with the cost of land which they would possibly not require at all.

Riggs v. Elmore's French Copper Depositing Company.—This was an action by the plaintiffs to have it declared that the sum subscribed for certain debentures was returnable in proportion to the amount of their subscription. The French Company proposed to issue £65,000 first mortgage debentures, and they issued circulars inviting shareholders to subscribe. It was stated that if the debentures were not fully subscribed the amounts would be returned to the subscribers. Only £2,000 or £3,000 was subscribed. That was paid into a bank. Under the circumstances the subscribers (of whom the plaintiff was one) applied for a return of their subscriptions. The Company went into liquidation, and the bank claimed to have a lien upon the sum in respect of overdraft. After some discussion, the defendants agreed to judgment, the money to be returned to the subscribers.

Luton.—A model electric light installation has just been finished at The Larches, Luton, the private residence of Mr. J. H. Green. The plant consists of a 3 h.p. nominal "Otto" gas engine, shunt-wound dynamo, and Epstein cells. The total number of incandescent lights is about 60, and the engine-house is about 50 yards from the main building, the lead-covered main conductors being conveyed underground across the lawn. The official trial of the plant took place last week in the presence of Mr. Albion T. Snell, the consulting engineer for the work. The London and Lancashire Electric and General Engineering Company, who have carried out this installation, have also been entrusted with the lighting of Lieut.-Colonel Martin's new residence, Petersham-terrace, Gloucester-road; Messrs. Wright, Layman, and Umney's premises, Southwark-street; and a special plant for organ blowing by electricity.

Lighting in Belgravia.—The Highways Committee of the London County Council reported on Tuesday last they had considered three notices from the Westminster Electric Supply Corporation of intention to lay mains (a) across Belgrave-road, (b) across and along York-street, south side, and across James-street, and (c) in Eccleston-street and place, Belgrave-square and place, Wilton-crescent, Halkin-street, Grosvenor-crescent and place, St. George's-place, and Piccadilly, from Apsley House to a point near Hamilton-place. The committee recommended that the sanction of the Council be given to the works referred to on condition that the company give two days' notice to the Council's engineer before commencing the work; that the details of the street boxes be submitted to and approved by him before the work is commenced; and that the covers thereof shall consist of iron frames filled in with materials to suit the paving.

Warminster.—The Local Board have discussed the question of an installation of the electric light for the lighting of the fountain in the Market-place, and the clerk has been authorised to sign an agreement with the railway company for the erection of a post on the company's premises for the carrying of the cable from Mr. Hill's premises to the fountain. The Chairman stated that he was prepared to carry a cable strong enough for a 2,000 c.p. light at his own cost. The question of the desirability of laying down a stronger cable in order to extend the light to two other points was then considered. The additional cost of having a stronger cable than that offered by Mr. Morgan was £16. It was generally felt that the stronger cable should be laid down, and that the question of extending the light to two other points should be left over for future consideration. Eventually it was decided to authorise the Lighting Committee to have the stronger cable laid down.

Factory Lighting.—The London and Lancashire Electric and General Engineering Company, Limited, have recently completed the overhaul of the main engines and machinery at the Bulbourne works of the Grand Junction Canal Company. Extensive alterations and additions to the plant have been made, including a complete system of electric lighting for the whole of the works, for which purpose it has been necessary to provide extra boiler power. To meet this want the company have put down a Davey Paxman boiler of the Lancashire type, 18ft. by 6ft. 6in., which besides supplying steam for the main engine, is of ample power to work a 6 h.p. nominal vertical slow-speed engine, belt coupled to one of the firm's new overtype shunt-wound dynamos, which can be utilised for accumulator charging purposes or supplying the lights direct. The wiring has been installed on the new water-tight system devised by Mr. C. N. Russell, the company's engineer, and as recently fitted by this firm at the Frogmore Mill, Hemel Hempstead.

Llandrindod Wells.—The clerk to the Local Board, at a meeting last week, read a number of communications as to electric lighting. He reported that a representative of the Severn Water Power Company, Shrewsbury, had made an inspection, with the view of utilising the River Ithon as motive power for generating electricity. The report of Messrs. Andrews and Preece, Limited, of Bradford, as to the installation of an electric lighting system was produced. A scheme for providing 2,000 8-c.p. lamps (which would yield a revenue of £1,000) would cost £4,000, and would entail an annual outlay, including repayment of capital, depreciation, wages, etc., of from £500 to £600. The price of the current was estimated at 9d. per Board of Trade unit, or equivalent to 4s. 6d. per 1,000 cubic feet of gas. The question of a generating station was not determined. The chairman and other members were in favour of having the whole question laid before and decided by a town's meeting. It was felt that the scheme was not yet sufficiently complete to do this. After full discussion, in the course of which a unanimous feeling was expressed in favour of the Board and not a company carrying out the work, it was resolved to defer the consideration of the subject pending the obtaining of further information.

Electric Communication Between Fire Stations.—The Fire Brigade Committee of the London County Council reported on Tuesday that early this year the Council authorised the provision of signalling apparatus at the 14 stations in the A district, in order to increase the facilities of communication between the superintendent and the stations under his charge, and to reduce the time occupied in sending on to fires assistance from stations adjacent to that at which the first call may be received. The system has now been in operation several months, and the chief officer states that it is of great advantage. The committee

accordingly proposed that it should be introduced at all other land stations of the brigade. The annual charge made by the Post Office for the apparatus in the A district was £81 15s. and it was estimated that the annual charge for the first seven years for the apparatus at the 44 stations in the B, C, D, and E districts would be £270. Against this, however had to be set a reduction of £80 in the annual charge for the telephonic apparatus at such stations. They recommended that subject to an estimate being submitted to the Council by the Finance Committee as required by the statute the offer of the Post Office to provide and maintain at the 44 stations in the B, C, D and E districts Stuart's signalling apparatus for £270 be accepted.

Lighting of Stafford. —As stated last week, an enquiry was held on the 13th inst. as to the application of the Town Council for sanction to borrow £20,000 for purposes of electric lighting. The Town Clerk, in stating the views of the majority of the Town Council with respect to the electric lighting application, said that the Council had called in Dr John Hopkinson to advise the gas manager upon a report which he had drawn up. Eventually, his report was presented to the Council, and had led up to this enquiry being held. The system to be adopted was the continuous current low tension method, with accumulators for light loads, and distribution by the three-wire system. Dr J Hopkinson who was called, stated that he had visited the site, and he considered it fairly convenient, and looked upon it as a great advantage that it was by the gasworks so that there could be some combination of the staff, and, in addition to that, a portion of the steam would be utilised for gasworks purposes. He had examined the plans of the buildings prepared by Mr Bell, after they had conferred together on the subject and they had his approval. The buildings would accommodate more machinery than it was proposed to purchase in the first instance, and would enable extensions to be made without further additions. He did not think they need spend more than £15,000 at the most to begin with, but would advise them to take powers to borrow £20,000. That would in no way interfere with the power of the Council to limit the expenditure.

Lighting of Bolton. —The ceremony of laying the memorial-stone of the new electricity works in Spa-road has just taken place. The ceremony was performed by Mr Alderman J Miles, J P, chairman of the Gas and Electric Lighting Committee. The town clerk Mr R G Hinnell) read a statement referring to the proceedings of the Council in the matter up to the present time. He said that the contracts for the plant had been placed with the following firms Steam engines and crane, Messrs. J and E Wood, £2,113 ; boilers, pipes, pumps, etc, Messrs. Hick, Hargreaves, and Co., Limited, £3,525 ; alternators and dynamos, the Brush Electrical Engineering Company, Limited, £2,257 ; high tension cables, Messrs. Siemens Bros and Co, Limited, £506 ; low tension cables, Messrs Siemens Bros and Co, Limited, £2,079 ; transformers the Brush Electrical Engineering Company, Limited, £550 ; switchboards, the Manchester Edison Swan Company Limited, Manchester, £930 ; accumulators, Messrs Crompton and Co, Limited £231 ; cast iron pipes, Staveley Iron Company Limited, £247 —£19,273. The works are expected to be completed and ready for supply of electricity early next year. The Mayor addressing the assembly, thanked the members of the committee for the devotion they had given, the time they had spent and the energy they had displayed in arriving at the best system, and obtaining all that would add to the success of the undertaking. The stone having been laid in position, Alderman Miles declared it to be well and truly laid.

London Electric Supply. —The Highways Committee of the London County Council reported on Tuesday that they had considered two notices from the London Electric Supply Corporation, of intention to lay distributing mains, etc in Dering street, Tenterden street, Harewood place, Princes street, George street, Fuller street, Maddox street, Mill street, and Brook street and also in another part of Mill street. The committee recommended that the sanction of the Council be given to the works referred to on the following conditions that the company give two days' notice to the Council's engineer before commencing the works; that the mains be laid under the footways and be kept 9in below the underside of the paving wherever it is found practicable to do so, that where the mains cross the carriageways they be kept at the same depth below the concrete or the road material as the case may be, that no pipes of larger size than 5in. shall be used, that no street boxes shall be constructed until the positions for, and the mode of construction of them shall have been submitted to and approved by the Council's engineer, that all pipes or openings from or into the boxes shall be of such shape as to remove all risk of injury to the covering of the cables; that all cables crossing the boxes shall be supported from below in the boxes, that all service lines or small cables shall be protected, where leaving the boxes, by an extra lead covering or by wooden stoppers, and shall also have a copper wire of sufficient size carried from the service to the main cable, in good connection with the lead or iron outer casing; and that the ends of all mains terminating elsewhere than in a box shall be securely protected by iron caps in addition to any other covering.

Cambridge. —The report of the Electric Lighting Committee of the Town Council with reference to the letter from the manager of the Cambridge Electric Supply Company Limited, dated November 2, which was considered at the last Council meeting, again came up for discussion last week. It was decided to refer the matter to the Lighting Committee for investigation. The Paving and Drainage Committee reported that they had considered the memorial from inhabitants of the borough asking that some provision might be made for the lighting of Parker's Piece, *and being of opinion* that the wishes of the memorialists would be met by the erection of a powerful light of 1,000 c.p. or 2,000 c.p. at the junction of the footpaths in the centre of the Piece, invited the gas company and the electric supply company to give them an estimate of the cost of the erection of such a lamp, together with the cost per hour when in use. In reply to the invitation of the committee, the gas company stated that they were at present unable to furnish an estimate for such a lamp. From the electric supply company the committee received an estimate, from which it appeared that the cost would be as follows: For erecting a lamp, complete £39 10s. ; for current per hour of a 10 ampere lamp nominally 2,000 candles, 2½d ; for carbons and attendance, per diem, 6d ; for cast iron pipes with two wires, 164 yards at 3s 9d per yard £30 15s. The company also intimated that they were prepared to supply the current for the first year free of cost, on condition that the Corporation would continue to pay for it after that time. The committee recommended that the estimate and offer of the company be accepted, and that they be directed to proceed with the work forthwith. The report was adopted.

The Blackpool Cars. —These cars are being temporarily worked by horses. A representative of a local paper has had an interview with Mr Councillor Pearson, chairman of the Electricity Committee. Mr Pearson said that the Council had been so erratic in their decisions that the committee had been placed in a very awkward position. In refusing to reappoint the electrical engineer as manager in charge of the tramway department, the committee were left without any responsible person to superintend the works. Yet they were bound to keep the trams going, and without authority from the Council they decided to employ horse traction. Mr. Pearson had full faith in the future of the Blackpool electric tramways. If they could obtain a perfect system the tramways could be made lucrative. The perfect system was that used at Budapest. He was in the South of France recently and took the opportunity of proceeding from there to inspect it. Through the medium of the consul he was introduced to the chief officials of the company which work this tramway, and he came away furnished with a mass of details respecting their system. They had 150 cars running regularly, over all sorts of points at all sorts of angles, and the system could have no higher recommendation than was bestowed upon it by Lord Kelvin, who remarked to Mr Pearson that it was the only perfect system of electric tramways which would be applicable to Blackpool. With regard to their present plant, the speaker observed that they had engaged Mr T. Parker, of Wolverhampton, to overhaul the whole of the line and electrical plant, and report to the committee. Then, with the Council's consent, they will ask Mr. Holroyd Smith the inventor of the system to overhaul it, for it was only due to him that he should have the chance. Mr Pearson's impression was that they will have to adopt a new system. In conclusion Mr Pearson said that it would be a couple of months before the report was furnished to the Council, and that in the meantime horse traction would be used.

Cork. —At a meeting last Friday of the Corporation, Mr Dwyer moved the suspension of the standing orders so as to allow the following recommendations of the Standing Committee to be dealt with "That the objections raised by the Board of Trade inspector to the scheme of the City Tramways Company, as approved by the Corporation, be answered as follows (1) That the Corporation is satisfied the branch tram through Marlborough street will be perfectly safe for the contemplated traffic; that unless this branch be sanctioned, tramway No 2 (to the Bandon and Passage Railway terminus) will be useless; and that the inhabitants of Marlborough street unanimously petitioned in favour of the tramway being laid through the street. (2) That the pressure of 500 volts as the potential of the electrical current be allowed in propelling the tramcars is set down as a maximum, that no regulations were stated to have been made on the subject by the Board of Trade, that a like maximum potential has been allowed in other towns, but the Corporation will assent to whatever potential may be decided upon within that maximum." The same committee on the 6th inst. included recommendation "That the order of Council of July, 1893, confirming recommendations of this committee in reference to the proposal to work the projected Cork tramways by electricity be amended, so that the Corporation shall sanction the working of same either by electricity or by horse power at the option of the promoters." Mr Rawe moved, and Alderman Hungerford seconded, the confirmation of the committee's recommendation, which was unanimously passed. Sir John Scott asked was there any possibility of the scheme being put into working order. Mr. J. W Bourke, solicitor, who attended on behalf of the company with reference to the matter, said certainly there was. They had been only waiting developments to know whether if they used electricity as a motive power they would get a return from the capital. They found that would be rather difficult, and they now proposed to make a tramway on a smaller capital which they hoped to have subscribed. A large portion had been already subscribed, and they would work the tramway by one horse cars.

Lighting at Weybridge. —The report presented to the Weybridge Electric Lighting Company by Mr A B W Kennedy, states that the present plant at Weybridge consists of two Thomson-Houston alternators, each having an output of 31 amperes at 1,100 volts, and each driven by a vertical compound steam engine made by Messrs. Bennett, Lindley, and Co., of Manchester, running at 240 revolutions per minute. The alternators run at about 1,500 revolutions per minute. Each alternator, if working at full power on an ordinary circuit, could keep about 900 8 c.p. lamps alight at the same time. The work done at the station is divided into two sections the private and the street lighting. For the former there is one main circuit each consumer having a

transformer on his own premises in the usual manner. For the street lighting there are three circuits. The public lighting is paid for by the local authority at the rate of £2 5s. per lamp per annum, which appeared to him to be a very low rate indeed. There are in all 119 lamps paid for in this way. Three other series lamps are separately paid for by individual consumers, and nine are used in the lighting of the station and the ground just outside it, making a total number of 131. As to the system adopted, Prof. Kennedy states that it is practically the only system by which at any reasonable cost the electric light can be introduced into a large and straggling district such as Weybridge. He concludes his report as follows: "I have no hesitation, therefore, in saying that if your demand for private lighting could be increased from the present number of 22 to about 75 or 80 consumers, assuming the average number of lamps installed by each one to remain as at present, the company would pay a small dividend on £16,000 besides putting aside a certain sum to reserve. The required increase in the number of consumers would not of course take place all at once, but if the matter were taken up locally, and pushed with vigour, I do not think that there ought to be much difficulty in obtaining the required increase. Of course the company might go on and pay its way, without making a profit, with a much smaller number of houses connected, but I believe that the number I have mentioned is about the smallest which would enable a reasonable dividend to be paid. On the other hand, after this number was once reached, any increase in the consumers would be accompanied by a very much larger proportionate increase in the profits." The lighting inspectors have accepted the offer of the Weybridge Electric Supply Company for renewal of lighting contract, subject to the wires being laid underground.

Lighting of Harrogate.—A scheme for the electric lighting of the borough, projected by Mr. George Wilkinson, M.I.E.E., consulting engineer, has been adopted by the Corporation. The scheme is intended, first, to produce and supply the electric light at a cheap rate so as to compete with the existing gas supply, which is in the hands of a company; and, secondly, to deal in an effectual way with the refuse collected from the ashpits of the borough. The results of exhaustive experiments made by Mr. Wilkinson on an extensive scale demonstrate, it is claimed, that town refuse, when put through a process of sorting, sifting, and drying, has a well-defined value as a fuel for generating steam power. The method hitherto adopted in many towns of placing the crude, wet, unsorted, material into immense brick kilns or furnaces, where it roasts for a time and smoulders, has not been found very suitable for generating steam. The capital cost of dust destructors is heavy, the combustion obtained owing to the presence of a large amount of moisture and incombustible matter is but feeble, and as a consequence the gases evolved are said to be deleterious to health. The system resorted to by Mr. Wilkinson is novel, and is a departure from all the methods of dust destruction hitherto adopted, and the correct term for this plant would appear to be the "refuse utiliser." The process in outline is as follows: The refuse is brought in carts or otherwise, and tipped upon a platform, whence it is automatically carried into a rough sifting apparatus which separates the old pots, cans, etc., the smaller material passing through the sifter and into a large hopper, from which it is forced in regular quantities into a drying cylinder, which extracts nearly one-third of its weight in the form of moisture. It then passes on to another sifter which takes out the fine dust, the resultant fuel being passed down a shoot and automatically injected into the special boiler furnaces. The dust is said to form a valuable manure, and the metal separated from the refuse is reduced to copperas by a simple process, whilst the rags are available for paper manufacture. Doubtless the outcome of Mr. Geo. Wilkinson's scheme at Harrogate will be awaited with general interest. The Town Council have decided to illuminate a certain defined area in the town by electricity according to Mr. Wilkinson's system. Mr. Wilkinson estimates that a complete installation for the supply of the area fixed upon could be put down for a sum not exceeding £12,000, and the annual earning capacity of this installation at 7d. per unit was £2,333, the estimated annual working expenses of the plant if worked continuously was £2,234, but if worked at night only the estimated profits were £500 per annum.

Lighting of Chelmsford.—A special meeting of the Town Council was held last week to consider the recommendations of the Lighting Committee with regard to the provisional order which is being sought by the Chelmsford Electric Lighting Company, and the requirements of the Board of Trade on the same. The first matter to give rise to discussion was the demand by the Board of Trade that the overhead wires should be placed underground; and while the committee recognised the advisability of adopting this order with regard to the principal thoroughfares, it did not consider the change necessary with regard to the less frequented roads. Mr. Chancellor reminded the meeting that in 1892 the company expressed its readiness to place the wires underground in the course of two years, and he was anxious to know why they were not now prepared to carry out their undertaking in full. Mr. Brittain explained that the committee had not deemed it necessary to put the company to the expense of placing all wires underground, and Mr. Tanner broadly hinted at the possibility that if the Council put the company to this very heavy expense, it might result in the withdrawal of the electric lighting of the town. Mr. Brown observed that he had gathered from enquiries he had made that to place the whole "electric system" underground would put the firm to an outlay of £23,000. The Lighting Committee, he said, were unanimous in their resolve not to put the company to any unnecessary expense. Mr. Bond directed attention to the value of the firm of Messrs. Crompton and Co. to the town, and he felt it would be nothing short of a calamity to Chelmsford were those works closed. A recommendation that the matter of the underground wires should be left to the judgment of the Board of Trade was accepted by a substantial majority of the Council. The offer from the electric lighting company to renew their contract for lighting the borough under arrangements as at present existing was next considered. Mr. Brittain moved, and Mr. Brown seconded, that the contract in question should be renewed. The resolution was adopted. On the matter of the provisional order for which Messrs. Crompton are now making application, and a draft of which was before the meeting, Mr. Chancellor opened the discussion with the declaration that no gentleman present understood the draft of the provisional order, and moved that the Council should employ an expert to advise them in the matter. The Town Clerk reminded the meeting that the provisional order was very similar to the license now held by Messrs. Crompton, and upon which they had already been advised. The only matters of real importance were the clauses dealing with the period that it should hold good, and the terms of purchase, should such at any time be deemed necessary. Mr. Duffield contended that the document deserved very careful consideration, and, in view of the lateness of the hour, the meeting should be adjourned. This course was adopted.

Walsall.—The General Purposes Committee of the Town Council reported last week that they had had before them a long report of the electric lighting scheme, proposed by the Electric Lighting Sub-Committee. They recommended that such report be adopted, and that the Council apply to the Board of Trade for approval of the adoption of a system of electric lighting for the borough on the principle suggested in such report—viz., high tension, with transformers; and also apply to the Local Government Board for their sanction to a loan of £19,650, in addition to the estimated value of the suggested site at the Wolverhampton-street gasworks, for the cost of carrying out the proposed scheme. The committee also recommended that the Council should enter into contracts with the Electric Construction Company, Limited, for the electrical plant for the sum of £10,003; with Messrs. Bumsted and Chandler for the engines, for the sum of £1,350; and with Messrs. H. and T. Danks for the boilers for the sum of £805, as soon as the approval of the Board of Trade and the sanction of the Local Government Board is received; and, further, that the Electric Lighting Sub-Committee be empowered to do all things necessary for carrying out the works mentioned or referred to in the above-mentioned report. The Town Council adopted the report. At the same meeting the Streets Committee reported that they had received from their electrician, Mr. Frederick Brown, a letter respecting the electric trams. Mr. Brown stated that he had kept a constant supervision over the running of these trams during the last 11 months, and that the running on the whole has been very satisfactory. Continuing, Mr. Brown says: "There have been a few cases where the cars have been hauled in through slight accidents in the mechanism, and three times the trolley wire has been down in that period, but no damage has been done to either person or property. There has also been some little trouble with the insulation of the feeders. Messrs. Callenders have been down and replaced one length along the bottom of Bradford street, near the Midland yard. The fault here was caused by wet getting into the joint box at the foot of the pole, and the water travelling along the strands of the cable caused a fault some yards along; this piece has, however, been taken out. The fuse box at the corner of Blue lane has also given considerable trouble; a new pattern has been designed and put in, making the connections much more secure, and giving much greater freedom for testing than the old one. I think now there will be little, if any, further trouble in this respect. I have communicated with Mr. Dickinson many times, and particularly about the safety of the wire where it is attached to the insulators. These points he has recently overhauled throughout the length of the line, and he assures me that they are in better condition for standing the winter storms than they were when first put up. As you are aware, the number of passengers has increased very considerably, the number being 2,245,660 in 1893, against 1,871,816 in 1892. So far as I can gather from the public expression of opinion, everyone seems well satisfied with the change from steam to electricity, and the 'unsightliness' of the wire appears to be completely forgotten or overlooked. I may here again call your attention to the fact that I have several times had the whole of the current through me, so that I have no hesitation in saying that there is not the least cause for apprehension with regard to the severity of the shock to any human being. I mention this particularly so that firemen or policemen may have confidence in cutting down a wire if it should be necessary. It is possible that, should the wire be accidentally broken and fall upon a horse, the shock would be sufficient to knock him down; this is the only fear I have for the future. If the tramway company can keep a pretty good supervision over the line, the trouble from this cause will be reduced to a minimum." This report was adopted. The Town Council granted permission to the South Staffordshire Tramways Company to fix feeder boxes under the footpaths in the borough.

Lighting of Fleetwood.—The Highway and Lighting Committee of the Town Improvement Commissioners on the 29th ult., recommended that the following tenders for electric lighting be received: Messrs. Parsons and Co., Messrs. Siemens Bros. and Co., Messrs. Greenwood and Batley, Messrs. Andrews and Preece, and the Brush Electrical Engineering Company. On the 5th inst. the same committee again considered the tenders and correspondence, and Mr. Dawbarn, from the Brush Electrical Company, Limited, attended for interview with the committee. It was then recommended that the report to the Board from this

committee upon the proposed installation of electric lighting in this district should be drawn up by the chairman of this committee and the clerk, and that the report, including the recommendation of a tender for the same (excluding buildings) should be laid before the Board at the next meeting. Last week the Improvement Commissioners had before them the report in question. The report stated that the committee, after investigation, coupled with the results of inspection of various electric lighting stations, were now in a position to offer recommendations. The chief object had been to secure for the town the best system, consistent with (a) moderate capital expenditure, (b) economical working expenses, (c) reliability and safety. It was the opinion of the committee that the superintendence of the requisite work should be placed in the hands of a competent resident working electrical engineer, and that such engineer should have charge of the works during construction, and afterwards take entire control of the department. Since the order was obtained over 16 complete schemes had been submitted to the committee. The original tenders were based upon the use of steam power, but ultimately the committee invited tenders, coupled with the information as to successful installations which had been obtained. Information was supplied to six selected firms, and complete tenders were invited concerning the building and site for station. The buildings and foundations for the machinery were recommended to be erected in the town's yard, London-street, and this portion of the work should be let by tender to local builders. The motive power recommended was to be provided by means of producer gas plant, working suitable gas-engines. The system recommended to be adopted is the high tension alternating system. With regard to public street lighting, provision was made for all the present street lamps to be lighted by electricity, ordinary streets to have 16 c.p. lamps, and the esplanade 32 c.p. Two large arc lamps were to be provided. The lamps numbered 232, and the committee reported the proposals contained in the tender they had decided to recommend were entirely satisfactory. Tenders were received as under: Messrs. C. A. Parsons and Co., Newcastle; Messrs. Siemens Bros. and Co., London; Messrs. Greenwood and Batley, Leeds; Messrs. Andrews and Preece, Bradford; and the Brush Electrical Engineering Company, London. The recommendations of the committee to the Board were: (1) That the tender of the Brush Electrical Engineering Company be accepted. (2) That, subject to consent being obtained, the requisite instructions be given for the preparation of the plans, sections, specifications, etc., required for the electric lighting station and gas tank in the town's yard, together with the construction of transformer chambers in streets. (3) That the committee be empowered to invite applications for the appointment of a resident working electrical engineer and to report to the Board upon the applications. In conclusion, the report stated the total capital required for the complete installation would not exceed £11,000, and it was believed the scheme would prove not only self-supporting, but in a short space of time would be working at a profit. The question of fitting up consumers' premises by the Board's workmen had not escaped attention, and the proposals of the committee upon the question of payment for the electric current and payment of the fittings by instalments, would be reported at an early date. The report is being printed, and copies are being supplied to the members with the clerk's analysis of the tenders. The report is to be considered at a special meeting of the Board.

PROVISIONAL PATENTS, 1893.

DECEMBER 12.

23857. **Apparatus for generating electricity.** David Cook, 30 Lancaster park, Richmond, Surrey.

23862. **Improved means for the automatic regulation of the position of the brushes of dynamo-electric machines and electromotors.** Ernest Hamilton South, St. Helens, Westwood park, Forest Hill, London.

23881. **Improved method of and apparatus for heating metals electrically.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Lewis Coffin, United States.) (Complete specification.)

23883. **Improvements in relays for use with alternating currents also applicable to vibrators.** Hermann Aron, 6, Lord-street, Liverpool.

23897. **Improvements relating to electric signalling or the transmission of information and energy by electricity and to apparatus therefor.** Charles John Reed, 45, Southampton buildings, Chancery-lane, London. (Complete specification.)

23902. **Improvements in and relating to electric motors.** William Phillip Hall, 45, Southampton-buildings, Chancery lane, London. (Complete specification.)

23913. **Improved process and apparatus for dissociating soluble salts by electrolysis.** Reginald Haddan, 18, Buckingham street, Strand, London. (Henry Spencer Blackmore, United States.) (Complete specification.)

23914. **Improvements relating to the insulation of submarine and other electric cables.** Jules Auguste Bisson, 18, Buckingham-street, Strand.

DECEMBER 13.

23951. **Telegraphic apparatus.** Thomas Bassnett, 15, Water-street, Liverpool.

23962. **An electric fire-escape.** Alfred Charles Hewitt and George William Pyke, 56, High-street, Maidenhead.

24001. **An automatic thermo-electric lubricating apparatus.** John Coombes, 8, Quality court, Chancery lane, London. (Rupert Napier Coombes, Western Australia.)

24017. **Improvements in or relating to processes and apparatus for obtaining and depositing metals by electrolysis, and in the treatment of the metals after leaving the electrolytic bath.** Ernest Stouls, 55, Chancery-lane, London.

DECEMBER 14.

24035. **A combined regulating switch, and motor for actuating same.** George Combe and Siemens Bros. and Co., Limited, Penny Bank chambers, Halifax.

24055. **A means of governing or controlling automatically the electric current generated by a dynamo or electric generating machine.** John Henry Cooper, 25, Roches street, Limerick.

24081. **Improvements in the manufacture of carbon for electric lighting and other electric purposes.** Regin Niewerth, 37, Cursitor street, Chancery lane, London.

24104. **Improved combined tidal motor dynamo-electric generator and storage batteries.** Robert Dunbar Radcliffe, 45, Southampton buildings, Chancery lane, London.

DECEMBER 15.

24131. **Improvements in or appertaining to the electro-deposition of zinc.** Matthew Andrew Mosley, Robert Wright, and John Henry Richardson, 20, Charles street, Bradford.

24154. **Improvements in electrical guides or indicators and batteries therefor, specially applicable for carriages and the like.** Ronald Leighton Grahame and Edward Smelter Cadman, The Limes, Teddington.

DECEMBER 16.

24217. **Improvements in electrical measuring instruments, and apparatus for use with alternating currents.** William Edward Ayrton and Thomas Mather, Central Institution, Exhibition road, London.

23234. **Improvements in the manufacture of filaments for incandescent lamps.** Alfred Charles Cossor, 21, Finsbury pavement, London.

24241. **Improvements in primary batteries.** Henry Weymersch and Edwin Freund, 40, Great Smith-street, Westminster.

24243. **An improvement in electrical arc lamps.** W. H. Lander, 33, Blessington-street, Dublin.

24271. **Improvements in and connected with telephonic apparatus.** Clement Bonnard and François A. Piat, 4, South street, Finsbury, London. (Complete specification.)

24274. **Improvements in apparatus for the electrolytic decomposition of metallic salts.** Carl Kellner, 46, Lincoln's inn fields, London.

24276. **Improvements in apparatus for electrolytic purposes.** Herbert Guthrie, 46, Lincoln's inn fields, London.

24285. **Improvements in means for connecting or supporting electroliers, brackets for electric lamps, or the like to or from ceilings, walls, or other places of support.** Henry Edmunds, 47, Lincoln's inn-fields, London.

SPECIFICATIONS PUBLISHED.

1893.

757. **Electrodes.** Barnett.

758. **Electrodes.** Barnett.

3488. **Telephones.** Forbes.

15519. **Electric engines.** Barker. (Lawrence Electric Company.)

18482. **Determining the presence and intensity of atmospheric electricity.** Opperman.

19789. **Electric railways.** Pitt. (Universal Electric Company.)

20069. **Controlling electric currents.** Lundell and Johnson.

NOTES.

The Poor Man's Light.—Foreign-made matches.

"Those Electric Belles."—The ladies of the ballet.

Many of Them.—A happy and prosperous New Year to all.

He Receives a Shock.—The reader of an electrical contemporary when he finds stale news in it every week.

Sparks from the Anvil.—An inventor has not applied for a patent for obtaining electricity from a cat's tail.

Those Falls Again.—A Swiss electrical engineer states that there is no connection between the Falls of the Rhine and the Falls of Niagara.

The Brush Diary.—We have received from the Brush Electrical Engineering Company, Limited, a handy diary for 1894 for the vest pocket.

South London Railway.—The City and South London Railway Company report that the traffic during the holidays was about the same as last year.

He Saw Stars.—But it was only his friend Brown who had placed the knocker in an electrical circuit in conjunction with a metal plate laid on the steps.

Telephony between St. Martin's and New York. The attempt made yesterday to telephone from St. Martin's-le-Grand to New York was unsuccessful.

Across the Channel.—A Parisian friend writes to say that it is incorrect that a French syndicate intend to construct an electric railway between Calais and Dover.

Not any Longer.—We understand that an electrical contemporary is not to be published any longer. This is gratifying news. The paper is already long enough.

The Engineering Laboratory at Cambridge.—Prof. J. A. Ewing in the *Times* of Wednesday makes an appeal for funds in aid of the engineering laboratory at Cambridge.

Spanish Nuts.—A Spanish correspondent contradicts the rumour that most of the electrical work in Spain is being carried out by French firms. He says that the Teutons are doing it.

Diamonds.—Some people are experimenting in the direction of making diamonds by electricity; others are producing electricity from diamonds, but these are, of course, "black diamonds."

The Torpedo Did not Arrive.—Our German correspondent informs us that there is no foundation for the statement that an electric torpedo is to be despatched from Kiel to the mouth of the Thames.

Proposed Exhibition.—It is stated that the idea of holding an industrial exhibition at Cardiff, and which originated with Mr. Ross, electrical engineer at Cardiff docks, is likely to assume practical form.

Thousands of Volts.—An American professor is reported to have taken thousands of volts. This is quite insignificant; many people, according to the sporting papers, have taken hundreds of thousands of vaults in this country.

Mechanical Traction on Tramways.—In view of the proposed adoption of cable haulage of tramcars in Newcastle, a local paper has this week published two articles on this subject—comparisons being made of steam, horse, cable, and electric systems.

The E.P.S. Blotting-Calendar.—The Electrical Power Storage Company, Limited, have forwarded us one of their combined desk blotting-pads and diaries for 1894, and giving particulars of the E.P.S. batteries for lighting and traction purposes.

Cost of City Lighting.—The accounts of the Commission of Sewers are very interesting as a financial record. The consolidated account contains the following item: Lighting, £22,477 (which shows a considerable increase on account of the electric lighting).

He Didn't Mind 1,000 Volts.—"You don't mind getting 1,000 volts," remarked a central-station engineer to a friend to whom he was showing the back of the main switchboard in the station. "No, not at all," was the reply; but I prefer to receive it at my house transformer—stepped down."

Clarke's Tables.—We have received a new and enlarged edition of this pocket-book, published by Messrs. Bush and Co., 93, Fleet-street. These tables are not directed mainly to electricians, but to plumbers, though a new section devoted to electrical matters has been added. The tables are such as appeal to practical men.

Water Power in Switzerland.—It is announced that the question of monopolising by the State of all the Swiss water powers will be seriously proposed in the spring session of the Swiss Federal Council. The Federal Council commissioned Mr. A. Jegher to make an inspection of all the water forces in the country, and to draw up a report for use at the forthcoming discussion of the proposed law.

Cable Communication.—The Hon. Mackenzie Bowell, Canadian Minister of Commerce, in an address delivered recently before the Honolulu Chamber of Commerce, referred to the necessity of cable communication between Canada, Hawaii, and Australia. He announced the conference which is to be held on the subject in Canada next year, and invited Hawaii to send a representative.

Small Industries at Niagara.—The Cataract Construction Company anticipate that there will arise at Niagara a number of small businesses in the machine line which cannot afford to erect a shop. To accommodate these the company propose to erect a large building, furnish it with shafting, divide it off into rooms, provide it with power, and lease floor room as may be desired. The power will be electric.

The "Medical Battery" Company, Limited.—At Marlborough-street police court on Wednesday, Mr. Hannay resumed the hearing of the charges of conspiracy to defraud brought against Mr. Cornelius Bennett Harness, the managing director of the Medical Battery Company, Limited; Mr. James Montgomery M'Cully, a physician; and Mr. Charles Beavington Hollier, a salesman. The proceedings were again adjourned.

Traction at Dudley.—The Dudley and Wolverhampton Tramway Company are about to apply to the Board of Trade for sanction to construct a tramway from the Dudley-road to Bilston. This line will probably connect with the Dudley and Wolverhampton service, and the terminus at Bilston will be outside the Town Hall. It is suggested that it would be a decided improvement if the tramway company would adopt electricity in preference to steam power, as at Walsall.

Gas Explosion at Glasgow.—On Tuesday an explosion of gas occurred at a manhole in Renfield-street in connection with the system of lighting the streets by electricity. Fortunately, no one was hurt; but as many of the footpaths are underlaid by cast-iron troughs containing the cables, and as accumulations of gas are frequently occurring in the troughs, the accident caused

much excitement. This is the third explosion of the kind that has taken place within a short time.

Storage Battery Traction. — Experiments are being made at Oneida, N.Y., with a street car propelled by a motor energised from storage batteries made by the Syracuse Storage Battery Company. The total run on one charge of the batteries is stated to have been 125 miles. The car makes daily from 64 to 90 miles without a break in the service. The 125-mile run was made on a seven-hour charge. There are 96 cells used in the car. The motor is a single 30-h.p. Rae type.

Train-Lighting.—The penny-in-the-slot apparatus is now in full operation in the carriages of the District Railway, but a daily paper submits that the lighting cannot be considered satisfactory. The intention was that the light should only fall on the book or newspaper of the person who dropped in the penny; but the apparatus is said to be so placed that when the compartment is full the light neither benefits the person sitting next the window nor his next neighbour, but falls between the two.

Scenic Effects.—The electric light plays a fairly prominent part in the scenic effects of "Robinson Crusoe," at Drury-lane Theatre. Portable batteries are used for, among other purposes, illuminating shells carried in the ballet and for head decoration. At the Lyceum, where "Cinderella" is being produced, electricity also occupies a fair position. The electric light is used with great effect in the ballroom scene, the garden background being lit with tiny electric lamps, while the slipper dropped by "Cinderella" in her flight flashes with electric light.

Oxford Local Exams.—The thirty-sixth annual report of the delegacy has just been issued by the secretary to the delegacy, Mr. H. T. Gerrans, M.A., Worcester College. It states that in electricity and magnetism the knowledge shown was poor. The definitions of magnetic lines were very loose and inexact; the explanations of the action of an ordinary electric machine omitted all reference to induction, and the function of the points on the prime conductor, the properties of solenoids—indeed, solenoids themselves seemed unknown.

Junior Engineering Society.—At the last meeting of this society, Mr. Percy Waldram in the chair, a paper was read by Mr. S. Cutler, jun., on "Coal-Gas Manufacture, and Recent Improvements of the Plant Employed therein." In conclusion, the cost of manufacture, by-products, the future of gas considered in respect to electricity, and gas employed as a heating agent were touched upon. The next meeting of the society will take place on January 5th, at the Westminster Palace Hotel, when a lecture on "Boiler Incrustations and Deposits," by Prof. Vivian B. Lewes, will be delivered.

Obituary.—The death of Sir George Elliot removes another of the band who were connected with the laying of the Atlantic cable. In July, 1892, Mr. Cyrus Field died; Sir J. Anderson, and now Sir George Elliot have followed. In the expedition of 1857 one half the cable was supplied by Glass, Elliot, and Co.—since then converted into the Telegraph Construction and Maintenance Company—the other half by Newall and Co., so that the cable was supplied by two firms whose principal partners were Tyneside men. Sir George Eliot retained to the last his interest in submarine telegraphy.

Electric Mail Cars.—Two electric postal cars, to be run in connection with the street-railway service, for carrying the mails between the post office and the several railway stations, have just been built at Ottawa. The Postmaster-General entered into a contract with the street-railway company to try the experiment, with a view to the system being introduced in other cities in Canada where the street-railway service was operated by electricity. The cars are equipped with 30-h.p. motors, and the result has been satisfactory. The postal authorities estimate that where it took 20 minutes to convey mails from the post office to the railway station by the old system, the same service can be performed now in five minutes.

American Wiremen to be Licensed.—The New York Board of Underwriters have authorised the president of the board to address a communication to the Governor of the State of New York calling his attention to the enormous increase in late years of damage by fire, due largely, in the opinion of the underwriters, to the improper wiring of buildings for electric light or power, and asking his influence to secure legislation which shall require that no person shall be permitted to wire buildings for electric light or power purposes who has not been duly licensed as competent to perform the task by some board of control competent to test the qualifications of applicants for licenses, as is now the case in connection with engineers having charge of boilers, etc.

They Dined in the Chimney.—The Brooklyn City Railway Company are introducing the trolley system on a large scale. The chimney at the power-house is said by the engineers to be the largest chimney yet built in cubic capacity, the inner core, or chimney proper, having 65,800 cubic feet of air space. The stack is 293ft. high, the sides of the base measure 38ft. 3in., and taper in to a height of 85ft. where the circular form is assumed. The iron cap surmounting this big stack weighs about five tons, and is 27ft. in diameter. The chimney is designed to carry away the smoke and gases from 36 250-h.p. boilers using forced draught. The new power-house was designed by Mr. F. S. Pearson, of Boston. To celebrate the completion of the chimney, a dinner, to which about 60 guests were invited, has been given in its interior.

Electric Light and Architecture.—Mrs. Meynell, in an article in the *Pall Mall Gazette*, on "The Light—That Queen of Colours," states that the bad old fashion of lighting from above is reappearing with the general use of electric light. That most beautiful illumination would leave nothing to be desired were it always placed with care. As for its shading, it must be hoped that this is not often omitted, as one has unfortunately seen it, in nurseries. When gas is done with, we shall be rid of an illuminant that never went well with architecture or with natural things. The electric light goes as well with them as moonlight. In the old Grand' Place at Brussels the high masts, carrying a ball of the blue-white electric light high in the air, give an entirely appropriate beauty to the faces of the ancient Flemish Gothic houses. Electric light would look in place in a deep-sea cave if it could be got there.

Telephony at the Antipodes.—So rapidly is science extending its conquests (says a Melbourne paper) that many sheep stations which were formerly only connected by the dreary tramp of the sundowner are now linked together by the telephone. So long as a squatter keeps his telephone on his own property he is quite within his rights, but if his wires cross a public road he renders himself amenable to the law, which forbids a private person to erect a telephone or telegraph, the monopoly being reserved for the Government. The Postmaster-General does not wish to prohibit telephones under such circumstances, and he has therefore had regulations prepared, which have been passed by the Governor in Council, charging a license fee of £1 per mile per annum for the first four miles, and after that 10s. per mile; the fee, however,

in no case to exceed £7 per annum. The height at which the wire must be carried across roads is specified, and it is also provided that in no case shall a fee be charged or accepted for the use of the line.

Railway Station Lighting.—The railway terminus at Liverpool-street will, when the addition is completed, cover no fewer than 15 acres of land. The arrangements for the electric lighting of Liverpool-street are on a large scale. Facing High-street, Shoreditch, is the building which contains the generating plant, which will brilliantly illuminate nearly 15 acres. This erection is surmounted by a shaft 150ft. high. It contains three 35 nominal horse-power compound engines by Davey, Paxman, and Co., with Crompton dynamos, and other engines will, it is expected, soon be added. Liverpool-street and the goods and passenger stations at Bishopsgate-street Stations will be lighted from the same building. Accumulators will be used as regulators. The station will be lighted by means of arc lamps, while the offices and hotel will be illuminated by incandescent lamps. In no greater degree has gas been so thoroughly superseded, and in addition to this it is proposed to apply the electric current for the transmission of power to cranes, ventilating-fans, etc.

A Large Electric Railway Project.—It is stated that Mr. Foster, ex-Secretary of the Treasury, is at the head of a syndicate to build an elevated electric railway between New York and Chicago, and they announce that, although the cost is expected to reach £20,000,000, they have already succeeded in interesting enough capital to ensure the consummation of their plans. The plans of the company propose a double track line to be built entirely of steel. By the elevation of the tracks there will be no grade crossings or other obstructions to a high rate of speed, and it is expected that the new line will be able to afford a passenger-train schedule of over 100 miles per hour. The syndicate have already secured patents for devices to prevent the cars leaving the tracks, and there can be no collisions, as no switches will be permitted on the road, the intention being to use it for passenger and mail traffic only. The present plans of the company contemplate a route that will embrace New York, Philadelphia, Pittsburgh, Cleveland, Sandusky, Toledo, and through to Chicago. It is expected that the run from Chicago to New York will be made in 10 hours.

Lighting Street Gas-Lamps by Electricity.—An electrical system of gas-lighting for city streets which operates devices located miles from a central station, without any electrical connection between them, is reported to have been introduced by the Cutler-Hammer Manufacturing Company, of Chicago, Illinois. This system discards overhead wires and the underground circuit, and adopts a new method. Each lamp is supplied with two sal-ammoniac batteries and a spark coil placed in an iron box buried in the ground at the foot of the post. In the lantern is a miniature gasholder of about two cubic inches capacity, pivoted on a hinge and held down by weights, and directly over this holder is an automatic gas-lighter, similar to those used in houses. Two wires about 10ft. long connect the lighter with the batteries through the post. Such an installation is under control from the gasworks. When it is desired to light the lamps of a city, it is only necessary to open the valve connecting one of the large gasholders at the works direct with the gas-mains. This results in a decided increase of pressure in the gas all over the city, sufficient to cause all the little gasholders in the lampposts to lift up about one-eighth of an inch against a platinum stop, and thus close the local battery circuit at each post. The automatic lighter being then supplied with current, immediately turns on and lights the gas.

Electric Lighting of Ships' Magazines.—Since the adoption of the electric light on men-of-war inconvenience is said to have often been caused through the sudden failure of the dynamo or some other portion of the electrical circuit, and which has put a ship in temporary darkness. The Admiralty, having recognised that the sudden failure of the electric light in the magazines and shellrooms might lead to confusion and become a source of danger in action unless some alternative means of illumination were provided, have issued instructions that in all ships in which the magazines or shellrooms are electrically lighted the lighting is to be so arranged that the electric lights and candles can be used at the same time and separately. Experiments have been carried out in the "Hood," "Grafton," and "Thetis," and no difficulty in these ships has been found in keeping candles burning in the present pattern light-boxes, provided the watertight doors of these boxes are left slightly open and the perforated doors are closed. In ships where difficulty is experienced a special kind of lamp, as used in coal-bunkers, will be provided. It has been decided to supply for use in the more important magazines and shellrooms a portable electric hand-lamp, about which further instructions will be given after experimental trials have been made.

Electrical Conductivity of Flames and Gases.—Mr. A. de Hemptinne deals with this subject in the *Zeit. Physikal Chem.* He so connected two platinum electrodes, one with a galvanic element and the other with a capillary electrometer, that the presence of a conducting substance between them was indicated by the mercury in the electrometer assuming a negative charge and moving upwards in the capillary. No effect was noticed when the electrodes were immersed in nitric oxide and oxygen gases in the act of combining, even when the E.M.F. employed was 100 volts. The same negative result was obtained when the reacting pairs of gases were hydrogen bromide and chlorine, and hydrogen chloride and ammonia. The influence of temperature was noted by placing the electrodes at the same relative part of a Bunsen flame, the combustible gas containing variable quantities of an indifferent gas. The hydrogen flame and the carbonic oxide flame conduct well, the conductivity increasing with rise of temperature. Observations were also made on the conductivity of explosive mixtures at the moment of explosion. There is decided conductivity in the case of oxygen-hydrogen and chlorine-hydrogen explosions, and a much slighter amount in the case of oxygen-carbonic oxide. Although hydrogen chloride and ammonia show no conductivity by themselves at moderate temperatures, dissociating ammonium chloride conducts fairly well. Ammonium bromide behaves similarly, but vapour of amylene bromide, although it is dissociated, does not conduct. Nitric oxide is a non-conductor.

An Imposing Catalogue.—The seventh edition of the catalogue of electrical supplies and wiremen's sundries just issued under the title of "Electricity" by the General Electric Company, Limited, forms a handsome volume of nearly 500 pages, containing numerous illustrations throughout. This edition has been rendered necessary by the many inventions and improvements introduced in the company's manufactures during the past two years, and the present catalogue deals with all kinds of supplies required by contractors for the interior wiring of houses. On turning over the first pages one finds descriptions and illustrations of switchboards for practically all purposes. Next come switches, and of these there is a very large variety. The company divide them into two classes—namely, main switches and branch switches: the former are for 20 amperes and upwards, and the latter

circuits of smaller capacity. These switches are again divided into single pole and double-pole switches. Following these is an extensive collection of wall plugs, ceiling roses, combination sliding pendants, cut-outs, and lampholders. We next find the "Robertson" incandescent lamp, which is now being made in two types—viz., those of long life and those termed economic, and of candle-powers ranging from 8 c.p. to 50 c.p. Passing on from lamp sockets, the catalogue then considers ammeters, voltmeters, and testing instruments, Byng arc lamps, projectors, and resistances; and plans, hints, and estimates for wiring houses are given. The volume next deals with the concentric system of wiring, insulators, tools, dynamos for different purposes, secondary batteries, boilers, turbines, fixtures, etc. The concluding parts of the catalogue, which will prove of great value to contractors, deal with electric cooking apparatus, bells, telephones, medical apparatus, etc.

A Large Water-Power Scheme.—Some time ago Mr. Thomas Oddy, electrical engineer, of Rochdale, received instructions to prepare specifications and estimates for the utilisation of waste water power for electric lighting and power purposes in Southern India. The project was to transmit 12,000 h.p. from some extensive waterfalls to two large towns some distance away. The towns in question are so far apart and away from the falls that it will necessitate a cross-country power transmission line (poles and conductors) being laid, 110 miles in length. Some idea of the magnitude of the scheme will be understood by the following abstract from Mr. Oddy's report: 3,000,000 cubic feet of water per minute is precipitated over the falls, with a clear drop of 200ft.; 12 1,000-h.p. turbines will be required, 12 towers, 10 bridges, 144 alternators, motors, and dynamos, of an average capacity of 250 h.p. each; telephonic communication from end to end and at five intermediate stations; 3,300 poles; 24,000 miles of wire made into cables; two large central-station buildings, two transformer stations; 96 transformers of 250 h.p. each; massive switchboards, weirs, flumes, sluices, etc. The whole scheme when completed will cost £350,000. After making allowance for interest on this loan, paying £10,000 as a yearly instalment to decrease loan, paying working expenses, inclusive of cost of maintenance, and depreciation of plant, machinery, and buildings, a profit of £7,000 per annum is anticipated. The current will be utilised for power and lighting purposes in cotton mills, corn and rice mills, for domestic purposes, in machine shops, for pumping, working cranes, hoists, mineral-mining and coal-cutting, haulage of canal tug-boats, tramways, and various other purposes. Mr. Oddy is now also engaged on a similar scheme for some public authorities in Southern Russia. This project is for transmission of 5,000 h.p. a distance of 93 miles.

Electricity in Mining.—As mentioned in our last issue, a paper has been read by Mr. R. H. Wynne before the North Staffordshire Institute of Mining and Mechanical Engineers at Stoke-upon-Trent on "The Application of Mechanical Arrangements in Underground Operations." He said that the subject might be classified, as far as regarded motive power, in the following divisions: (1) Horse power, (2) steam, (3) compressed air, (4) electricity, (5) combustion of petroleum. Electricity as a medium for the transmission of power had not by any means attained its fullest development, but during the past four or five years its use for colliery purposes had received an immense impetus, and there was no doubt, the author remarked, that it would become in a short time the medium *par excellence* for the transmission of power over long distances underground for a variety of purposes—*e.g.*, hauling at far-away stations where the main haulage worked from the surface or engine at the bottom of the shaft was not conveniently applicable, pumping water from the bottom of inclines under similar circumstances, and actuating drilling and coal-cutting machines. It also afforded the means of obtaining superior lighting on the surface and in the main roads underground, and most likely in the near future a portable and safe light for the working collier. The advantages of an electric system for districts not easily accessible to direct steam-power or compressed air motor might be summarised thus: a reduction in capital expenditure when compared with other systems; facility in putting conducting cables down shafts and laying them underground to distant motors, small loss from resistance in cable or leakage of current to the earth, compared with waste in the compressed-air system; lowness of cost of maintenance; speed with which an electric plant could be erected and set to work. The breakage of a cable and the sparking therefrom was a contingency to be considered. Although the advantages of electricity were considerable, he stated that it was doubtful whether it would be good policy to adopt such a system where steam could be used direct from the surface for haulage purposes; but there did not appear to be the least doubt of the value of electric motors in situations not suitable for other mechanical power.

The Blackening of Incandescent Lamp Bulbs.—"I have repeatedly noticed," writes Mr. W. Stuart-Smith, in the *Electrical World*, "discussions as to the cause of blackening of incandescent lamp bulbs. The latest theory seems to come from France, and is to the effect that residual oxygen in the bulb, together with that which was occluded in the filament, attacks the carbon and forms carbonic oxide, which undergoes dissociation by coming in contact with the comparatively cold glass, depositing the carbon and leaving the oxygen free for a repetition of the process. It has been some years since I have paid attention to chemical matters, but, unless I am mistaken, cooling as above would not cause dissociation, and the above explanation cannot be the correct one. It seems to me that a portion of the action at least must be due to the following cause: It is well known that all substances in the solid or liquid form give off vapour; in fact, are surrounded by an atmosphere of their own vapour. If the substance is confined in an airtight space, the vapour density is definite for every substance and for every temperature, but varies greatly with the temperature, being much greater for high temperatures. For a given substance and a given temperature the vapour density will be the same, no matter what other gases may be present; but if other gases are present in considerable quantities, considerably more time will be required for the density to reach its maximum value. In a vacuum, on the contrary, the action is comparatively rapid. Carbon, when cold, is a very stable substance, and its vapour density very low; but at the high temperature of the white-hot filament vaporisation must be comparatively rapid and the vapour density relatively great. As the hot vapour comes in contact with the cooler glass it will deposit, and thus vaporisation, instead of stopping, as would be the case if the glass were the same temperature as the filament, continues while the lamp is burning. When the lamp is extinguished the vapour in the globe must deposit on the glass until the definite density of the vapour of the cold carbon is attained. The more rapid blackening when the lamp is new may be due in part to the better condensing action of the clean glass, and it may be due in a greater part to the fact that some portions of the filament are more easily volatilised than others, and the action consequently more rapid while these are being thrown off."

REGINALD J. WALLIS-JONES.

Reginald John Wallis-Jones, A. M. I. C. E., M I E E., was born in Liverpool in 1863, and was educated at Christ College, Brecon (under the head mastership of the present Bishop of Bangor), going through a special course of chemistry and physics there. His technical education was then continued by going through the whole course of the School of Telegraphy and Electrical Engineering at Hanover-square; in July, 1881, passed the final examination (first class) in the theory and practice of electric light, telegraphy, and telephones; also passed the speed standards in telegraphy, single-needle Morse mirror and syphon recorder. In May, 1883, he obtained a certificate of first class (honours) from the City and Guilds of London Finsbury College (under Prof. Ayrton) for electric lighting and transmission of power, and also went through the mechanical engineering shops at King's College. Since 1881 Mr. Wallis-Jones has been actively engaged in practical work, first joining the staff of the Anglo-American Brush Company, where he was engaged in the test-room and factory, and then on installation work, such as lighting of Messrs. Peek, Frean, and Co., and the Waverley Station, Edinburgh. He resigned this post to accept the position of inspecting electrician on the staff of Robert Hammond, Esq., and was employed on various contracts, such as lighting of Blair's, Stockton, Bolckow Vaughan, Leslie's Shipyard, Newcastle, etc., and in 1882 came to London for the Hammond Electric Light Company. In 1883 was transferred to the Metropolitan Brush Electric Company; established and managed the Milford-lane central station for them; lit up Covent Garden Theatre; maintained plant of the Royal Mint, Holborn central station, etc. Resigned his appointment in 1884 to rejoin the Hammond Electric Light Company. Among other work, lit up the Theatre Royal, Birmingham, tested all the work for rewiring of the First Avenue Hotel. In the beginning of 1884 was offered an appointment on the staff of Woodhouse and Rawson; superintended for them several important contracts, such as the erection of the first overhead mains for the Grosvenor Gallery electric light station, lighting of reservoirs at Crossness for the Metropolitan Board of Works; contracts for Guinness and Co., Lord Brassey, W. H. Smith and Sons, etc.; and in 1886 went to Portugal for this company to erect plant for the lighting of the Port de Leixoes. In 1887 Mr. Wallis-Jones was appointed engineer and manager of the contract department of Messrs. Woodhouse and Rawson, Limited, and went to Barcelona to design the system of electric lighting for the central station there. He has designed and patented several improvements in electrical apparatus, such as an automatic earth detector, recording voltmeter, fuses, surgical lamps, etc.; and in conjunction with Mr. Stepney Rawson compiled the well-known "Woodhouse and Rawson wiring table." In 1882 Mr. Wallis-Jones was elected an associate member of the Institute of Electrical Engineers, and in May, 1889, was elected an associate member of the Institution of Civil Engineers, while in 1889 he became a member of the Institution of Electrical Engineers. His connection with the Old Students' Association is well known. In 1888 he was awarded the medal of the institution for the best paper of the year, which was entitled "Some Installation Breakdowns." In the beginning of session 1890-1 he took up the work of honorary secretary to the association, and the following figures speak for themselves as to the work done: "Last session 62 new members were elected," and up to December 31, 1891, the date of his resignation (the session ending in October, 1892), 38 members and associates were elected. In December, 1891, owing to pressure of professional work, Mr. Wallis-Jones had to resign the honorary secretaryship. Since the failure of Woodhouse and Rawson, Mr Wallis-Jones has been connected with Messrs. Waller, Manville, and Kincaid.

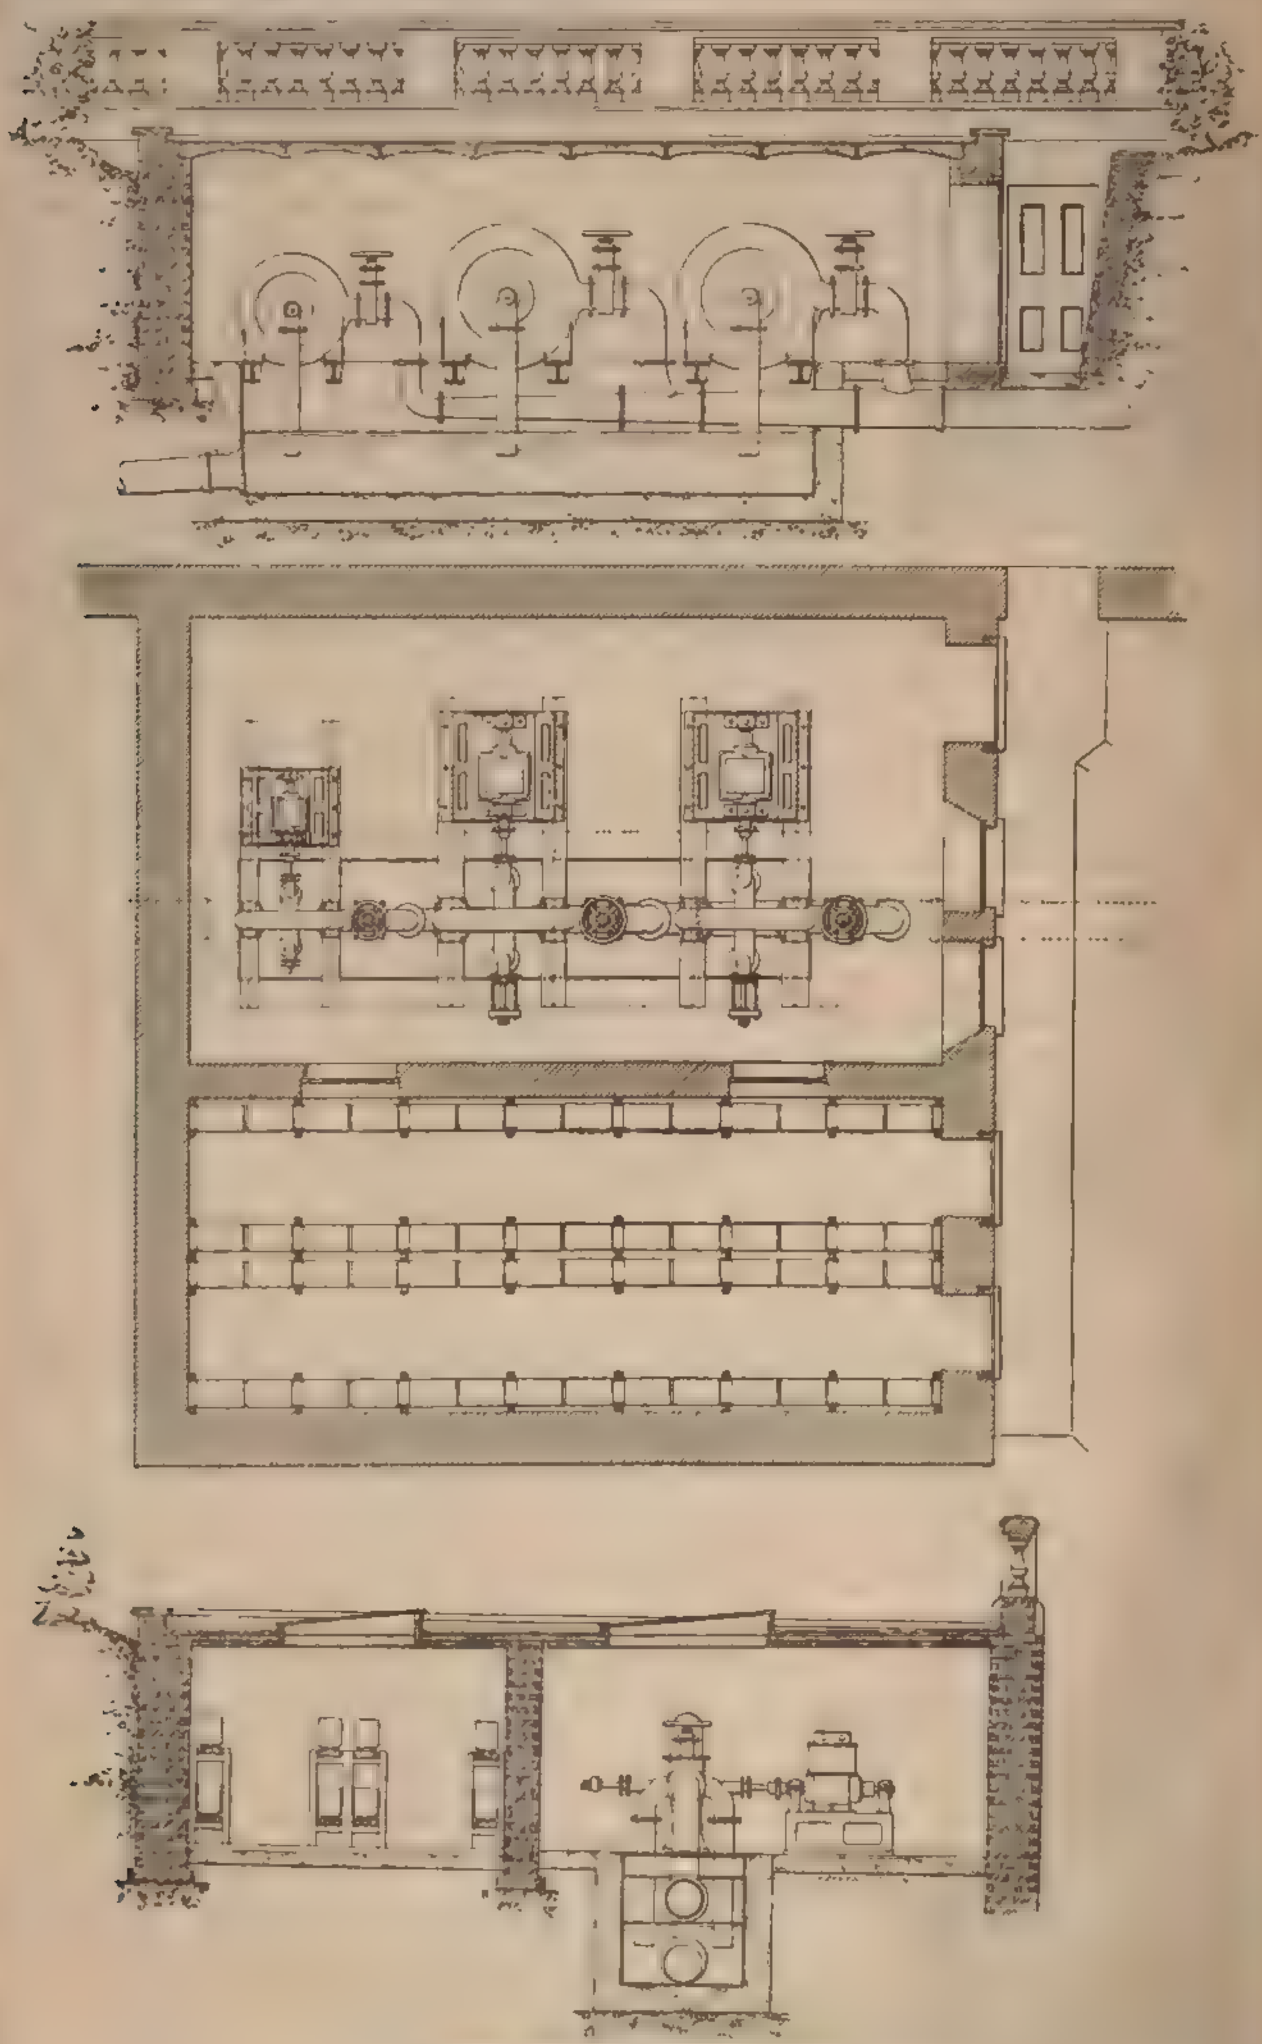
ELECTRIC LIGHTING AT CHATSWORTH.

We have been favoured with a brief description, with illustrations, of the installation designed by Mr. B. Drake, and carried out by Messrs. Drake and Gorham, at the historic mansion of Chatsworth. It has been Mr. Drake's object to reduce the whole arrangement to one of absolute simplicity, as he attributes his success in the large number of country house installations which he has laid down to the elimination of any complicated apparatus which is likely to become deranged. He contends that it is always more easy to arrange a complicated apparatus than a simple one, and it will be seen that at Chatsworth the whole of the lighting requirements of a large country house have been met, and the plant is so simple that no skilled labour is required in its manipulation.

At a height of some 400ft. above Chatsworth House there exists a lake of some nine acres in extent, to which a pipe was laid some years ago for the purpose of supplying water to the well-known Emperor fountain. Mr. Drake found that by tapping this pipe he could obtain up to 150 h.p., or sufficient for all the lighting required. The turbine-house has been excavated entirely out of the solid ground, and being surrounded by shrubs it is entirely out of view from every side. Provision is made in the turbine-house for two turbines, each of 50 h.p., and one of 20 h.p., of which the third turbine is not yet completed. The dynamos are coupled direct to the turbines, forming a very neat and compact arrangement which is not likely to become deranged. From the dynamos the current is conveyed to switchboards, by means of which the supply from the house can be drawn from either of or all the turbines according to requirements.

Adjoining the turbine-house is the accumulator-room containing 60 accumulator cells for supplying the requirements of the house when the turbine is not at work. These cells are charged from a separate machine during the hours of lighting, so as to reduce the item of labour to a minimum. To avoid the complications due to the supply of current from a dynamo which is charging the accumulators owing to the rise of E.M.F., according to their state of charge, the switchboard has been arranged so that the small machine can be employed for charging the accumulators, while the house circuit is run direct from the larger machines, which are connected either singly or in parallel as required. The arrangement also provides for the small machine and the accumulators being worked together in case of emergency for the supply of the house. Precautions are taken in the switchboard to prevent any accident due to the switches being moved in the wrong order. Owing to the high fall available, special precautions had to be taken to prevent any sudden stoppage of the water which would produce a jar on the pipes. A previous attempt to provide a valve at the lower end of the pipe so as to avoid having to climb the mountain whenever the fountains were required, has entirely failed from this cause. To meet this, a 3in. by-pass is provided for every valve, so that after the main valve has been closed the by-pass can be manipulated. This expedient has been found to be thoroughly successful.

The turbines used are of the Vortex type, by Messrs. Gilkes, of Kendal, and arranged to run at 1,000 revolutions per minute, the dynamos being manufactured by Messrs. Siemens Bros. The roof of the station is composed of concrete, carried by iron joists, and the whole plant runs so noiselessly that at the distance of a few feet from the turbine-house it is impossible to tell whether it is running or not. In addition to the pipe which carries away the water from the turbines, a large safety opening has been arranged to guard against any accidental flooding of the turbine-house.



CHATSWORTH ELECTRIC LIGHTING

The current is conveyed underground, by armoured cables more than ½in. sectional area, to a point in the centre of the building, from which the whole distribution to the different rooms is effected, every circuit being carefully numbered, so that it can be controlled at will. There are also switches placed throughout the building in convenient places so as to take full advantage of the ease with which electric light can be lit or extinguished. The voltage at the house is maintained at 105, and the whole of the wiring is on the parallel system. The accumulators are of the "D. P." type, capable of discharging at 120 amperes for four hours

In the general arrangement of the lighting Mr. Drake's object has been to utilise all the handsome old fittings, for which purpose a special imitation electric candle has been introduced, which so nearly resembles wax in colour and texture that it is impossible to distinguish the two when placed side by side. Where fittings have been added, the style of each room has been carefully studied and the fittings made to harmonise with the architectural requirements, the metal work being entrusted to Messrs. Hart, Son, and Peard. In many of the rooms, such as the oak-room, where metal work would have been out of place, the lamps have been skilfully embedded in oak carving worked into the orignal panels, by which arrangement the lamps are almost invisible in the daytime.

WHAT IS ELECTRICITY?—VI.

BY SYDNEY F. WALKER.

THE ATTRACTIONS AND REPULSIONS OF ELECTRIFIED BODIES.

Though every part of this subject is very difficult, at first sight probably that portion which the writer has chosen for the subject of the present article presents more than the usual share of difficulty, because, apparently, the phenomena of the attractions and repulsions of bodies electrostatically charged stand quite apart from the other electrical phenomena with which we are familiar. These phenomena would appear also to be in somewhat the same category as those presented by the force of gravity, in that we have only been able to say hitherto that they existed, without explaining why they existed. If it should prove that the theory is correct which the writer has ventured to put forward as accounting for the various electrical phenomena, may it not be possible that the line of thought induced may lead us even to the explanation of the causes of the force of gravity itself?

If the views which the writer has enunciated are correct, it follows that everything in the universe may be referred to two elements—matter and energy; and that every substance we know of, every substance that exists, of whatever form, has taken the form conferred on it by the energy present—in other words, in accordance with the resultant of the forces present. In a non-electrified body, we have not a body at rest—there can hardly be such a thing in nature—but a body already in motion within itself, whose molecules are in motion, and not only in motion, but subject to different kinds of motion, in obedience to the different forms of energy already present. Thus, in the leaves of a gold-leaf electroscope, the gold leaves themselves, though apparently at rest, have their molecules in motion, due to the heat present, to the light-rays that are absorbed, possibly to sound-waves passing through them, and, further, to the motions to which they owe their being as molecules of the substance we know as gold. Further, the bodies around the gold leaves are not at rest. The metal conductor to which they are attached, the glass bottle that contains them, the atmosphere surrounding them, both within and without the bottle, all are subject to the same forces, all have their molecules in motion from the same or similar causes. And, as we know, the position of outward rest assumed by the gold leaves is taken up in obedience to the resultant of all the forces present, of the forces that have been described, and, in addition, the force of gravity, the pressure due to the weight of the surrounding atmosphere, and others.

The position of outward rest is a position of equilibrium so long as the forces present remain in the same proportion. If you alter any one of the forces present, if you bring another force to bear upon any part of the system, the equilibrium is destroyed, and you may have outward motion till a new resultant furnishes a new position of rest or equilibrium. If you cause a draught of air to be directed towards the gold leaves, they will be deflected both to one side or the other, or in opposite directions, according to the direction and force of the draught employed, till a new position of rest is found. If you pass a sound-wave through the gold leaves, say, by connecting a sounding body to the table of the electroscope, motion again results, though not in the same form. If you pass heat into the gold leaves, adding to the heat already present, motion again results, though, again, not in the same form as when you applied your draught of air. And so you may cause motion of the leaves in a number of different ways whenever you produce sufficient alteration in the position of equilibrium to cause motion of translation—motion from one position of rest, as we view it, to another.

One method, then, should be, if the writer's view is correct, that what we know as electricity is motion, to pass a charge of electricity into the gold leaves, and, as everyone knows, the result of such an operation is to cause a motion of the leaves, to cause them to diverge from each other. In this, as in each of the other cases, what we have done is, we have added a new motion, not only to the gold leaves, but to the atmosphere surrounding them, and to every body in the neighbourhood. In obedience to this added molecular motion, which is strongest in the metals because they are metals, because they are created to receive this motion we call electricity, and the other motions we call heat and sound, more readily than other bodies, weakest in the atmosphere surrounding the leaves and in the glass containing them, for the contrary reasons, visible motion of the gold leaves follow. We have added the same motion, and in even a larger proportion, to the metal conductor supporting the gold leaves, but no motion results, because the other forces present did not allow it. The gold leaves are more easily moved, because the effect of the other controlling forces, such as gravity, upon them is small. If we apply a controlling force of sufficient magnitude to resist the electrostatic force applied, we shall obtain no motion of the leaves, as, for instance, if we place the electroscope within a vessel containing air or other gases compressed above the ordinary atmospheric pressure. On the other hand, if we reduce the pressure of the atmosphere within the electroscope by creating a partial vacuum, we shall obtain an increased motion, other things being the same, for a given expenditure of electrical energy.

Again, as we know, if the temperature of the conductor of our electroscope is very low, we shall have difficulty in obtaining a divergence of the leaves, while if it be well heated first we obtain a divergence with comparative ease. What we do, then, when we charge an electroscope is to communicate motion, added motion, to all the bodies present; and this motion, expending itself on the molecules of the body, causing them to move not only within the body, but, in doing so, to expand the body, and the conditions being favourable to move it as a whole, causes the divergence we are familiar with. Just as the application of heat will cause light bodies—gold leaf, tissue paper, etc.—to move as a whole, so the application of what we call electricity to similar light bodies causes them to move—not in the same manner that the application of heat moved them, but strictly in accordance with the resultants of the whole of the forces present.

The above reasoning holds good for other light bodies—such as pith balls, feathers, the puppets that are made to dance by electrostatic charges, and others. The question of the attraction of oppositely electrified bodies for each other the writer hopes to deal with in the next article.

Edison Phonographs.—The Edison-Bell Phonograph Corporation have obtained an injunction against the Edison Phonograph Company, restraining the latter from infringing Mr. Edison's patents by the sale and use in England of a phonograph imported from America, and said to be made in accordance with the patents.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations, or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Other Places	4s. 11d.	9s. 9d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XI. of new series of "THE ELECTRICAL ENGINEER" *can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s.*

THE DAYS THAT ARE PAST.

The end of each year is, of course, an excellent "sermon time," and few persons are lucky enough to escape the outpourings of moralisers upon every subject and theme. The "gentle reader" will therefore doubtless be ready with due allowance of Christmas charity (or not, as he thinks fit) when he looks on this page expecting to find the customary number of paragraphs containing each a nice little moral wrapped up in a modicum of interest, wit, and wisdom. At the worst, then, we shall only try his patience more or less—perhaps, let us hope, rather less than more.

Seriously, however, those engaged in the electrical industry of Great Britain—to whom these columns more especially appeal—can and will of a certainty look back upon the past year as being the most important that they have hitherto seen. On the one hand, trade in general ebbed and flowed and ebbed again to a point in the curve of commerce whose equation is perilously near $\frac{1}{x}$; and, as a rule, when the volume of business sinks, or tangible profits grow small by degrees and beautifully less, the merchant, the manufacturer, the warehouseman, and the shopkeeper, with all their allies of industry, are obliged to cut down expenses to suit. If, therefore, electric lighting had not ceased to be a luxury, and attained the greater height of being an absolute need to suffering humanity, we should have seen a very considerable diminution in the amount of work accomplished in 1893 as compared with that of the previous year or two. But it is safe to say—even in the absence of definite reports from the firms and companies engaged in the trade—that capital progress has been made, and a considerable amount of solid work accomplished, the results being perhaps more satisfactory in proportion as the unreliable, badly managed, and thriftless concerns have dropped out of the struggle.

It might be of some interest to a few if we were to tabulate the actual progress of 1893—say, with regard to central-station work and the development of public lighting; but just as the figures in a charity sermon respecting the number of orphans to a fraction relieved per diem, etc., are not nearly so attractive as the rows of bright young faces themselves, we may leave the task, at any rate for the present, to the industrious compiler of illusory and incomplete statistics. He is certain to arise at an early date in the new year with promptitude only surpassing those others who hasten to contradict him. Figures, it is said, can never lie, though according to the gas journals (who for some curious reason entertain a feeling of jealousy towards electric lighting), the converse—that liars can figure—holds equally well.

There is, of course, one pre-eminent feature in the past year that has already began to effect progress of a type even more marked than the steady advance of the previous twelve months; but the subject of incandescent lamps, the expiry of patents, and all the rest of it, has become as cheap as the two-and-a-half watt twenty-five-for-a-sovereign lamps themselves; and not even an end-of-the-year moralising article will stand any more of it.

Enough now to say that, so far as mortal mind can postulate the course of affairs, we see at the present time the industry of electric lighting established not only *firmly*, but almost *freely*—that is, without any restraint but that of open and fair competition. So long as these conditions exist, we feel sure of continued trade prosperity in this direction for many years to come. Such prosperity may not—we hope *will* not—be too rapid of development: we have had a surfeit of 25 per cent. dividends paid (or, rather, declared) out of capital. The promoter (we use the word in its best sense) of electric lighting enterprises will be well advised if he keeps to a modest 5 to 10 per cent. return upon his capital; and this applies still more when the promoter is a public body.

Is it, we wonder, within the bounds of possibility that as we have thus written of electric lighting prospects—"front and back," as the Irishman said—so we may at the end of an early year also write with regard to the developments of electric traction and power uses generally? It would seem almost inconceivable that we should be able at the close of each year to chronicle great advances in electric lighting, whilst the equally wide-reaching developments of power distribution are almost non-existent. To-day, however, there is little or no progress to report in traction work. Early in the year came the opening of the Liverpool Overhead Railway, but since then the actions of the electric traction interests have been less prominent than their talk. Possibly the tongue in this case must precede the hand, but joint committees, or even modified draft rules from the Board of Trade, will never build or equip a tramway, although they may prevent its being done. Isn't it about time, good gentlemen, to get to work: and as soon as the ground is clear, and the "powwow" finished, may we not hope to give the horse a rest from his labours, so far as tramcar hauling is concerned? We do not, at any rate, expect to be satisfied with electrical progress until the "days that are past" have seen the opening ceremonies of more than one electric tramway, or other system of power distribution and utilisation.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

PROF. FORBES ON HIS CRITICS.

SIR,—As you are probably aware, I am not in the habit of answering anonymous personal attacks, but, in view of the possibility of other people sharing the opinions expressed by some of your contemporaries affecting my character for fairness, I beg leave to ask for space to publish one or two facts in your valuable and impartial journal. My critics have, without seeing the designs of Mr. C. E. L. Brown, endorsed the opinion that, in designing a 5,000-h.p. alternator, I have availed myself of the plans submitted by him to the Cataract Construction Company. I am quite sure that Mr. Brown would corroborate the statement that the general features of the designs are totally distinct. But my critics particularise the charge by saying that I have taken from Mr. Brown's design the idea of winding the armature with copper strip, insulated with mica. Is it claimed for Mr. Brown that he is the originator of such a proposal? Mica insulation is largely used in the States; and further than this, I have in my office the drawings of the first 5,000 h.p. alternator which I designed long before Mr. Brown got out his design, in which the winding above referred to was adopted. In my latest design, however, it happens that the armature is wound with cotton-covered copper wire, No. 0 B. & S. gauge. It is true that the fields are wound with copper strip, but the insulation is tracing-cloth. I submit that there is not the slightest foundation for the charge which has been made.

With regard to the charge made by Mr. Ferranti against the Cataract Construction Company, and supported by Mr. Crompton, in his usual courteous and gentlemanly language, by saying "that there had been a barefaced attempt to pick the brains of the world," it would be hopeless to ask whose brains they have picked, and what details of the system are due to them; but from the moment that the suggestion of such a charge was hinted at to me by Mr. Ferranti, I have looked into the matter, and the following statements are true:

1. With the design sent in by Mr. Brown there were two prices—one for the machine made in Switzerland, another for working drawings, with the object of manufacturing in America.

2. If the design of that gentleman, or any other manufacturer, had been thoroughly suitable for our case, that design would have been accepted, and the price quoted paid for it, whether it was made in America or Europe.

3. The Niagara enterprise is probably the first American enterprise that ever came to Europe, saying, "We have already subscribed our capital in America, and we are ready to exchange such portion of our cash as may be necessary to secure the brains to properly conduct our enterprise." I confess I am ashamed of my countrymen, and cannot imagine what is the animus which has led to so wilful a misconstruction of such liberality, foresight, and straightforward dealing.

4. It has been generally understood that no private undertaking has paid so much for engineering advice, in advance of contracting, as the Niagara project. Most of these disbursements have been made to English, Swiss, and French engineers, and they amount already to about 90,000dol.

These are facts from which your readers may form their own conclusions as to the animus which has actuated the critics of the Cataract Construction Company.—Yours, etc.,

GEORGE FORBES.

Westminster, S.W., December 27, 1893.

SHUNTS.

SIR,—I am greatly obliged to your correspondents "Sidney F. Walker" and "Sidelight" for the information they give me in connection with my difficulties, and also to you, Sir, for your remarks, which, to say the truth, are not much to my liking. Let me deal first with your reference to a contemporary, and that contemporary's reference to my letter. I may say that I never buy that contemporary, and I never met a man who did. I get it sent gratuitously, like most members of the industry, and think it a very wisely-conducted concern; better than a trade catalogue, because ordinary folk do not know how it is run and why certain interests are kept to the fore while others are in the background. But the trade knows, and laughs. Grub-street still exists, and writers can be bought and sold. This contemporary, with that flippancy so characteristic of it, says, "Of course, a shunt to a galvanometer always acts by lowering the difference of potential," etc. "Of course"—that is the usual flippant introduction. But "of course" is not found in the text-books, and I doubt if any scientific man of repute will be so ready to corroborate this "of course." If your contemporary is correct, perhaps it will indicate some text-book or some authority from which I may gain a little more information on this "of course." Perhaps it will be able to prove that practical folk do, after the insertion of a shunt, change the arithmetical value of the original E to something else, E_1. The

original formula is, say, $C = \frac{E}{R}$; putting in the shunt decreases R to R_1, and according to your critic changes E to E_1, so that we get a new formula with all three quantities varying, and $C_1 = \frac{E_1}{R_1}$. So far, all is good; but how am I to know what the new E_1 is to be? I cannot find any text-book that tells me to measure E_1. The fact is, your contemporary tells me that I am to find two unknown out of three; for C_1 is unknown, and, according to it, E_1 is unknown, and I only know R_1. Well, my mathematical knowledge is too feeble to tell me how it is done. Won't your wise contemporary just tell us? It is so knowing, and lays down the law so cavalierly, that it must know some book or paper which will help me. Let me put this case. I have a secondary battery with internal resistance practically negligible, and connect my galvanometer directly to its terminals by a negligible resistance. The pressure acting on the galvanometer is indicated by E. I now insert a shunt, say, of equal resistance to the galvanometer. Is the acting pressure, E, changed to E_1; and what is E_1? I find no text-book to tell me that E changes to E_1, and have always used formulæ similar to the following: (1) $C = \frac{E}{R}$; (2) $C_1 = \frac{E}{R_1}$; when E and R in (1) are known, and E and R_1 are known in (2). If E changes to E_1 in (2), in what text-book shall I find it explained? It is holiday time, and I cannot write more at present, though in another letter I hope to illustrate by means of a diagram what I understand takes place. Wishing you and your contemporary—which, though I hit at, I have a sneaking affection for—all the compliments of the season.—Yours, etc.,

H. L.

THE DYING OUT OF ALTERNATING-CURRENT WAVES.

BY A. E. KENNELLY.

It has been asked how many times an alternating current could be transformed through successive induction coils without losing its essential wave character.

If the induction coils have no iron cores, the case depends entirely upon the shape of the wave of E.M.F. impressed at the terminals of the first transformer. Supposing that this wave were sinusoidal, then after the permanent state of steady activity had been attained, all the currents and voltages throughout the series would be sinusoidal. There would be attenuation and change of phase along the series, but there would be no change of wave type, whatever the resistances, capacities, or inductances might be, provided these did not vary with time.

If the wave of E.M.F. impressed upon the first transformer were not sinusoidal, then, with iron still excluded, there would be a progressive change of wave type accompanying the attenuation and phase displacement. The change would be rapid in the earlier and more gradual in the more remote transformers. The finally surviving waves after an indefinitely great number of successive conversions, would be fundamental sinusoids *i.e.*, simple harmonic waves of the alternation frequency. The exact rate at which deviations from the sinusoid are absorbed depends upon all the conditions of the successive circuits, but is open to computation when these data and the initial wave outline are forthcoming.

If, on the other hand, the induction coils contain iron, new considerations arise. There will now be hysteresis and variable magnetic leakage to take into account. Owing to hysteresis, the currents will not be sinusoidal even if the first impressed E.M.F. be sinusoidal, and owing to this the drop of pressure in resistances will introduce a departure in the voltages from the simple harmonic type. The magnetic leakage, which varies during the cycle, also causes some deviation of a similar nature. But while this disintegrating influence is extending, there will also be a correcting tendency at work such as would be established by transformers without iron. Which of these tendencies will preponderate, whether the waves would become more and more distorted along the series, or more nearly sinusoidal, would depend upon all the circumstances of the circuits, of the quality of iron in the cores, and of the initial wave outline, but under ordinary conditions it would seem that the waves would never become truly sinusoidal, but would also never undergo great distortion.

Briefly, then, non-ferric induction coils would, in the permanent state, transmit an initial sinusoidal wave through an indefinitely long series of such coils, unchanged in type. They would also sift an initially non sinusoidal wave down to a sinusoid, so that practically the conditions might then be closely represented by a sinusoidal generator of reduced amplitude brought into operation further along the line, beyond the principal sphere of shifting action. With ferric transformers the case would be more complex, but, broadly, there would be a tendency for the sinusoid to survive.—*Electrical Engineer* (New York).

CHLORIDE ACCUMULATOR.

We have referred to this accumulator several times, and now give diagrams of the plate and of curves obtained. It will be unnecessary to enter fully into its composition, as this information will be found in our issue of November 17, page 461. Fig. 1 shows a plate, while Fig. 2 shows the curves obtained.

FIG. 1.

The diagram of curves shows the capacity of the chloride accumulator under varying conditions. These curves show the results of various tests. It will be seen by comparing

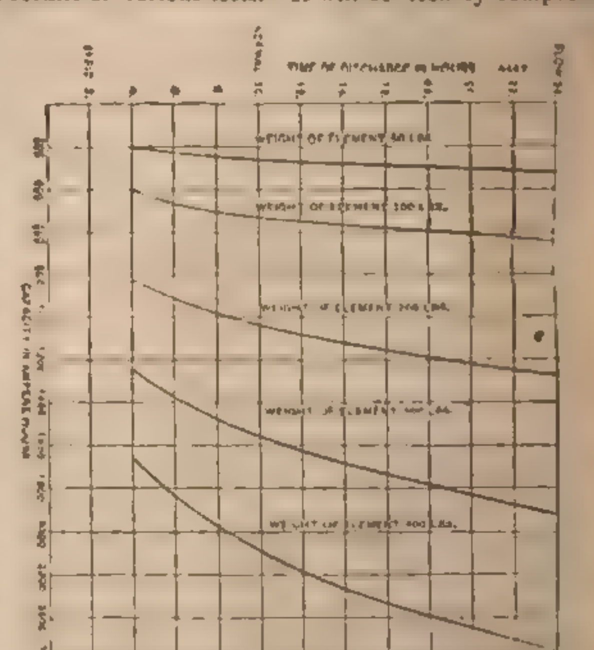


FIG. 2.

the different results that in every case there is shown to be a difference in capacity of only one third between the lowest and the highest rate of discharge. Thus, while the smallest element, weighing 50lb., has a capacity of 320

ampere-hours when discharged in 24 hours, its capacity is still as high as 210 ampere-hours when discharged in four hours, which is six times its previous rate.

UNIPOLAR AND NON-POLAR INDUCTION.

A paper on the subject of unipolar and non-polar induction has been read before the Electrotechnical Society of Berlin, by Mr. Friedrich Vogel, of Charlottenburg. The author referred to a paper on the subject of unipolar machines by Mr. Thom. Marcher, previously published in the *Elektrotechnische Zeitschrift*, which accorded in the practical results with experiments previously made by the author. The explanation given by Mr. Marcher of the behaviour of the magnetic lines of force, however, appeared to Mr. Vogel to be incorrect. The experiments carried out by the latter gave results which, although sufficiently

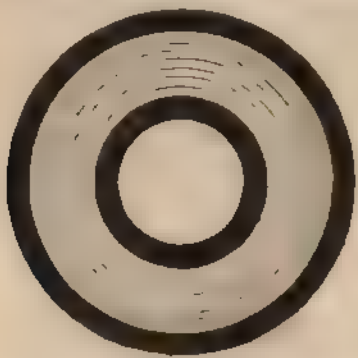

FIG. 1.

interesting theoretically, greatly reduce the value of unipolar machines for high tensions. In any case the unipolar machines, according to the French patent No. 181,787, the German patent No. 50,805, and the recent German patent application 72,048, and others, were theoretically wrong.

The author mentioned that, starting from a similar standpoint to that of Mr. Marcher, he himself tried to construct a practical unipolar machine. This, however, would not work.

The description of the experiments is so presented that a start is made from a machine which corresponds in principle with the foregoing patents, and then passes on to the changes conceived by the author, from which working results could at least be hoped for, if not expected, and finally deals with the experiments which allow of a definite decision respecting the course of the magnetic lines of force in the rotating armature.

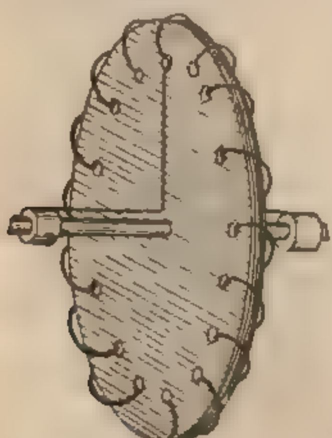

FIG. 2

Fig. 1 shows a plan of one of the magnets lying at the side of the armature. A disc of iron plates served as the rotating armature, which was bored in such a manner that the perforations lay in a circle concentrically to the axis of rotation and between both ring poles. The windings were led through these perforations—about 120—which continued in the style of a Gramme ring, and lay before the outer ring pole. The ends of the windings were led past the inner pole, as shown in Fig. 2, along the shaft of the machine to the commutator. The resistance of the armature winding amounted to 0·45 ohm.

We give one series of experiments which took place at the works of Messrs. Siemens and Halske at Charlottenburg. Accumulators were employed to excite the magnets, and a torsion galvanometer of one ohm resistance for measuring the current. The output of current at 2,500 revolutions was 0·006 ampere, and from this is calculated, with a total resistance of 1 + 0·45 ohms, an E.M.F. of 0·0087 volt.

In place of the whole winding a single wire was laid, which, as shown in Fig. 3, ran longitudinally with the axis through a perforation. The inner resistance of this wire could practically be left out of account. With this,

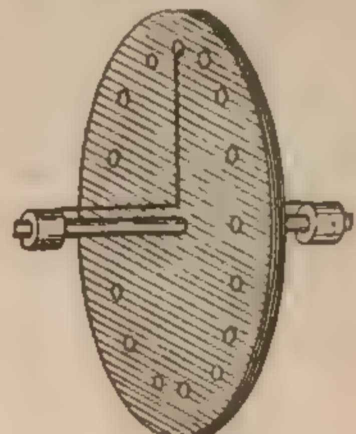

FIG. 3.

at approximately the same rate of speed and the same magnetisation, the output was 0·0082 ampere, or 0·0082 volt, or pretty nearly the same E.M.F. as the whole winding. In both cases the E.M.F. could only have been induced by the lines of force passing beyond the inner ring pole, and acting by induction on the leads to the commutators. If this supposition were correct, it would be necessary to strengthen the induction in order to improve the magnetic circuit from the shaft to the magnets. In order to obtain this improvement, screw keys were held on the bearing-pieces and back plates of the magnets, either towards only one magnet or towards both. The result for the whole winding at 2,500 revolutions was: 0·0063 ampere with a single and 0·0069 ampere with a double winding; the result with a single wire at 2,600 revolutions was 0·0082 ampere, and 0·0087 with a double.

Experiments hitherto have left it doubtful whether the E.M.F. is nil in the winding, because the armature iron, which contains perforations, takes with it the magnetic lines of force which pass from the closed-ring surfaces out-

FIG. 4.

wards through the armature iron, or if there be another cause. The author consequently caused to be made by the same engineer, Mr. Richard Galle, who had made the previous magnets, a pair of magnets, the circular dimensions of which were the same as those of the former, so that they suited the same armature. They differed, however, from those used in the first tests, as shown in Fig. 4, inasmuch as the pole surfaces were not continuous rings, but alternated

broad pole surfaces, with intervening spaces, which were cut in down to the back plate. With this arrangement, a pole surface on the inner crown always stood on the same radius as an intermediate space on the outer crown. The same coils as before, served in all the following experiments for the magnetic excitation, so that all the pole surfaces of the inner crown were of the same polarity as well as those of the outer crown. The armature iron furnished with perforations could no longer, therefore, take with it the lines of force, as the field magnets were also perforated.

From the experiments carried out it appears very unlikely that the failure of the previous unipolar machines with multiple winding is due to the magnetic lines of force being carried away by the armature iron. The result of the experiments is rather as follows:

The magnetic lines of force remain between the polar surfaces from which they spring. In the rotating armature iron the lines of force must go round about the perforations, thereby being torn away and causing eddies. These torn away lines of force induce in the parts of the conductors, which pass through the perforations in order to form a connection between the portions of the conductors led to the pole surfaces, exactly as high an E.M.F. as in the outer portions of the conductors, and they counteract each other.

A priori, this result is not quite to be understood. The lines of force only go to a small portion, corresponding to the specific magnetic resistances, through the perforations, and cut the conductor-pieces lying there. When the field-magnet poles consist of homogeneous rings or other revolving bodies, the distribution or field of force in the armature iron remains the same; yet the same acts by induction.

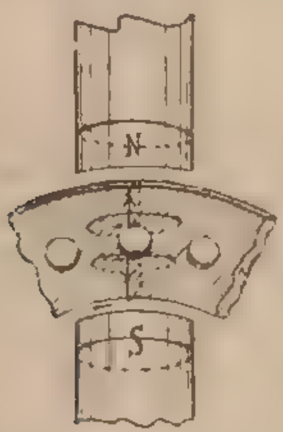

Fig. 5.

When the lines of force in the armature iron — as before, homogeneous pole rings — are in a stationary condition, the molecular currents travel from molecule to molecule at a constant rate of speed. It can easily be shown, in Fig. 5, that the forces which originate from those parts of the conductors carried through the perforations from the lines of force set up by the current in the armature iron, exactly counteract the forces which act between the outer portions of the conductors and the pole surfaces. In Fig. 5 the dotted lines indicate the portion of the conductors lying behind the plane of the paper, referring to circuit currents substituted for the magnetic lines of force. The direction of the current is shown by arrows on the conductors. As the forces counteract each other, there is no working output when the armature is rotated. Therefore in the whole winding there will be no current induced, nor can this, if furnished with current, work as a motor.

The author next returns to the substitution of the lines of force relative to the bodies magnetically excited by a circuit current in connection with non-polar induction.

The only working force which is exercised upon a complete winding or armature when current passes through it from the magnetic system, field magnet, and armature iron, is that the winding seeks to place itself parallel to the pole surfaces, and therefore perpendicularly to the direction of the lines of force. This working force, however, shows itself merely as pressure on the armature iron, not as turning momentum in the direction possible for the armature to move as tangential force.

The author made the following experiments at home which leave little room for doubt. He used a mirror galvanometer of his own construction, of high resistance and very sensitive, as the instrument for authenticating the resulting E.M.F. The magnets were excited by an accumulator. The field magnets employed were the same as before. On the one occasion those with continuous ring poles were used, and on the other occasion those provided with intermediate spaces. No difference was shown in the qualitative behaviour of the two magnets.

In place of the armature already referred to, the author made a new one, in which he used massive copper discs for the winding. These were insulated from the armature iron, and also from the shaft, and were screwed up to the armature core, consisting of discs made of iron plates.

The copper discs were somewhat amalgamated at the outer sides, so that the current might be better conducted. For taking off the current two systems of brushes were used, made of woven wire. One of these was in contact with the outer circumference of the copper discs, and the other in the middle between the outer pole and the inner pole, opposite the former.

In the first experiment the iron discs and the two copper discs had no perforations between the poles. It was very easy to collect current from each copper disc, and to prove that an E.M.F. was produced. This experiment corresponds completely with the Faraday induction in copper discs iron armoured. The E.M.F. of the two copper discs could also be placed in series.

In order to discover what influence a greater interruption of the armature iron would have on induction, the iron plates were perforated, while the copper discs were left untouched. The perforations lay about midway between the outer and inner poles. The result of the experiment was exactly the same as before.

Next, the copper plates were connected with each other by means of rivets passing through the perforations already made. If, now, the two E.M.F.'s in the two copper discs were not counteracted by a third formed in the rivets passing through the armature iron, they must be able to be put into series as soon as they were both connected at the brush system at the circumference with the galvanometer.

Fig. 6.

No working was, however, perceptible. On the other hand, when the two inner brush systems were connected by the galvanometer, the E.M.F. in the rivets could be proved.

The practical result arrived at by the author is the same as that of Mr. Marcher—viz., that all unipolar machines have hitherto rested upon false principles, in which an addition of E.M.F. in single parts of the conductor is striven against by leading the winding according to a Gramme ring through parts of the armature iron. As a theoretically interesting result, the author considers that the demonstration showed that, in fact, the magnetic lines of force continue through the iron, or, in other words, the analogy founded by W. von Siemens between magnetic occurrences and electric currents is the correct one (and confirms their introduction in the calculation of magnetic phenomena), and not the analogy with electrostatic influence.

The author also touched upon the non-polar induction in Faraday ring transformers, as the statement concerning the same by Mr. Marcher did not appear to be correct. The author starts from an induction coil, Fig. 6, the interior of which may or may not contain an iron core.

If a closed-circuit current be moved in even line in the direction of the axis of the coil out of the infinite to the position A_1, then the force exerted by the coil on the circuit current increases, and reaches its maximum in the neighbourhood of A_1, because here all the windings of the coils work in the same way in the direction of the movement. In the position A_2, on the other hand, the forces in the direction of the movement are counteracted as the circuit

current lies symmetrically to the single windings of the coils. The sign of the working of force changes from over this position. If the induced electric work be regarded as the equivalent of an applied mechanical work, then follows the known behaviour of the E.M.F. The forces are strengthened when bodies which can be magnetised are placed in the coil, as the resulting currents strengthen the working of the coil currents. The E.M.F. is therefore strengthened, but remaining nil in the position A_2.

The closed-circuit current does not behave the same if it be not moved parallel to the coils; but in the latter case the strength of current varies. In the position A_2, the forces parallel to the coil are nil; but forces work on each line element or circuit in the direction of the connecting line with the axis of the coils—these try to draw the circuit current together, and therefore to lessen the circuit, or *vice versâ*.

Consideration is next given to a ring inductor, which may have over all its circumference an evenly-distributed exciting winding, as shown in Fig. 7. In the same way as with a straightly-stretched inductor, a working of the exciting current is strengthened by the ampere molecular currents. The latter are replaced by the resulting currents, which pass concentrically to the exciting currents.

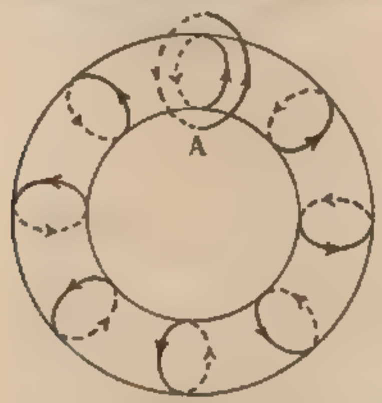

FIG. 7.

A circuit current, A, is found at the ring inductor in each position symmetrically with the circuit currents of the ring. Consequently, there is never exercised on the circuit current, A, any force in the direction of rotation round the axis of the ring. Consequently, no induction can take place in a circularly-arranged conductor if the conductor revolves round the ring.

It is obvious, however, that forces operate on the circuit current, A, which always fall in the level of the circuit current. Induction is also obtained if a wire loop is laid round the constantly excited ring, and the same be pulled together or pushed apart.

If changeable magnetisation lie under the ring, induction is set up in each circular-shaped piece of conductor which is laid on the ring.

The magnetic lines of force fill not only the iron of the ring, but also the surrounding space of the circuits of which the central points have their geometrical position in a plane which stands perpendicularly on the level of the ring at its middle points. If the excitation be changed, then the density of the lines of force is altered.

CYLINDRICAL COPPER CONDUCTOR RESISTANCE OF ALTERNATING CURRENTS.

In 1886, Lord Rayleigh gave a formula to calculate the effective resistance of a conductor of circular section through which an alternating current of given frequency passed. Unfortunately, the series which gives these values is so little convergent with the increase of the diameter and the frequency, that it is practically useless.

In his presidential address to the Institution of Electrical Engineers in 1889, Sir W. Thomson gave a table calculated for certain diameters and a frequency of 80, which extended the radius for practical work. From a practical point of view it is handy to have a table which will enable us to make the necessary calculations for all diameters and all frequencies, hence M. Hospitalier has in *L'Industrie Electrique* attempted to give a simpler formula and figures to facilitate calculations.

Let R_A be the resistance of a conductor with circular section carrying alternate currents, and R_c its resistance to continuous currents, then

$$R_A = k\,R_c.$$

where k is a numerical coefficient depending upon the frequency, $\frac{1}{T}$, and the diameter, d.

From Sir W. Thomson's researches it is found that for a given conductor this factor, k, is the same for each value of the product $d^2\frac{1}{T}$, whence it is possible to give in tabular form the values of k for each corresponding value of the product diameter by frequency. In the table given below diameters are in centimetres and frequencies in periods per second, the conductor being copper with a resistivity of 1,597 C.G.S. units. In order to get the factor, k, of a conductor, d, cm. in diameter, it is sufficient to multiply the square of the diameter by the frequency in seconds, and to find in the table the approximate value of k, which is then to be used in the equation.

VALUE OF COEFFICIENT k, with copper conductors of circular section of diameter d (cm.) traversed by alternate currents having a frequency of $\frac{1}{T}$ (periods per second):

$\frac{d^2}{T}$	k.	$\frac{d^2}{T}$	k.
0	1·0000	1620	1·8628
20	1·0000	2000	2·0430
80	1·0001	2420	2·2190
180	1·0258	2880	2·3937
320	1·0805	5120	3·0956
500	1·1747	8000	3·7940
720	1·3180	18000	5·5732
980	1·4920	32000	7·3250
1280	1·6778		

Example.—What will be the effective resistance of a copper conductor 2cm. diameter traversed by an alternate current of which the frequency, $\frac{1}{T}$, is 80 periods per second, the resistance, measured by a Wheatstone bridge, being three ohms?

We have $d = 2$; $d^2 = 4$; $\frac{1}{T} = 80$; $\frac{d^2}{T} = 320$.

From the table we find for this value (320) that $k = 1{\cdot}0805$.

Then $R_A = R_c\,k = 3 \times 1{\cdot}0805 = 3{\cdot}2415$ ohms.

If the value $\frac{d^2}{T}$ is not in the table, take the value next above. The error is in excess. The table is sufficiently extended for practical purposes, as it will give values up to 130 periods, and diameters up to 15cm.

When the quotient $\frac{d^2}{T}$ is over 32,000, the effective resistance is obtained with great precision by substituting for the solid a tubular conductor of the same external diameter and thickness equal to

$$6{\cdot}38\sqrt{T} \text{ centimetres.}$$

These results are for copper of the resistivity 1,597 C.G.S. units. A modification of the formula is necessary for other conductors, but as these are so seldom used, we have given only that part of M. Hospitalier's investigation which is directly practical.

THE PROPOSED PACIFIC CABLE.

During the late tour of Mr. Mackenzie Bowell, the Canadian Minister of Trade and Commerce, through the Australian colonies, a memorandum, drawn up by Mr Sandford Fleming, and containing definite proposals for the construction of a Pacific cable, was submitted by him to the Australian Governments. Copies of the memorandum have reached this country and enable us to form some more accurate idea than has hitherto presented itself of the cost of constructing and maintaining an alternative line of cable communication with the Antipodes.

Mr. Sandford Fleming, who was at one time engineer-in-chief to the Canadian Pacific Railway, has for many years advocated the construction of an entirely British cable across the Pacific.

His views were expressed at the Colonial Conference of 1887, and he is generally recognised as one of the best authorities upon the subject. He is therefore presumably in a position to authenticate the facts of his statement. His scheme embraces four alternative proposals for carrying a cable from Vancouver Island to Australia without landing on any territory which is not under British protection.

By the first route the cable would run from Vancouver Island to Fanning Island, thence to the nearest island of the Fiji group. From Fiji it may run direct to New Zealand and thence to Australia. The distance by this route is 7,145 nautical miles, and the estimated cost of construction £1,678,000.

By the second route the cable would run from Vancouver Island to an unoccupied island known as Necker Island, about 240 miles to the west of the Hawaiian group; from Necker Island to Fiji, and thence to New Zealand and Australia. The distance by this route is also 7,145 nautical miles. The estimated cost of construction is £1,385,000.

By the third route the cable would extend, as in No. 2, from Vancouver Island to Necker Island, and thence to one of the eastern islands of the Gilbert group. From the Gilbert group two branches would extend, one to Queensland touching at the Solomon Islands and having its terminal point at Bowen, one to New Zealand through Viti Levu, the southern island of the Fiji group. The distance by this route is 8,264 nautical miles. The estimated cost is £1,825,000.

The fourth route is identical with the third, except that it leaves out the branch to New Zealand and takes the shortest possible line from Vancouver through the Gilbert Islands to Bowen. The distance is only 6,244 nautical miles, and the estimated expense £1,380,000. But it has the disadvantage of leaving New Zealand dependent upon its present cable communication, and it excludes Fiji altogether from telegraphic connection.

The question of cost is, of course, a very important one. Mr. Sandford Fleming proposes to meet it by constructing the cable as the joint property of the colonies concerned, and raising the capital required on their joint guarantee, at an interest which he places as low as 3 per cent. In order to extinguish, as he thinks it may be necessary to do, the subsidy of £32,400 already paid by some of the Australian colonies to the Eastern Extension and payable until May, 1899, he proposes to purchase an annuity of the required amount for those years, and thus adds a capital outlay of £145,000 to the sum required for the construction of the cable. If this arrangement be applied to No. 2 route, the capital required will be £1,745,000, and interest at 3 per cent. will bring the annual charge to £52,350. Mr. Sandford Fleming has, he says, obtained estimates from the best authorities of the cost of working the Pacific cable under Government. These estimates include the salaries of all officials, the cost of two steamers for current repairs, and allowances for all necessary expenses at the terminal and mid-ocean stations, and the highest figure which they have been calculated to reach is £60,000. Besides working expenses it is proposed to establish a renewal fund of 2 per cent. on the cost of the cable, or £32,000 a year. The total estimated expense, including interest upon the capital, amounts, therefore, to £144,350 a year.

Against this outlay Mr. Sandford Fleming puts a carefully detailed calculation of possible revenue. He bases his calculation on the assumption that a Pacific cable may hope, when it is in complete working order, to take at least half of the messages now sent over the lines of the Eastern Extension Company. The number of words transmitted by that company last year was 1,275,191. Dividing this into equal parts, he takes 637,595 words as representing the probable business on which the Pacific cable would begin. But there is the increase of business to be taken into account. This experience is shown to be greatly stimulated by low charges, and from this cause alone, without taking into consideration the expanding trade of Australia and America, Mr. Sandford Fleming estimates that the normal increase will be much faster than it has been hitherto over the lines of the Eastern Extension Company. The charge per word of the Eastern Extension Company until May 1, 1891, was 9s. 4d. The normal increase under that tariff was 14 per cent. per annum. From May 1, 1891, until January 1 last the charge was 4s. a word. To have completely recouped themselves for the loss in fees, the expansion of business of the company should have been a little more than 100 per cent. As a matter of fact it was only 54 per cent. This was, however, enough to show that under a low tariff a considerably more rapid rate of increase may be reasonably counted upon. The charge which it is proposed to make over the Pacific cable is 2s. a word. Thus messages would pass by that route from Australia to England for 3s. 3d. a word instead of 4s. 9d., which is the present charge of the Eastern Extension Company. Putting aside, however, any fanciful estimate which might seem to be justified by these considerations, and basing his calculations on the assumption that business may stand still for three years and will afterwards continue only to increase at the normal high tariff rate of 14 per cent., Mr. Sandford Fleming works out the following table of the estimated earnings of the cable:

Year.	Words per [illegible]	Earnings at 2s. per word.	Year.	Words per [illegible]	Earnings at 2s. per word.
1894	637,595	£63,759	1900	1,175,176	£117,318
1895	726,858	72,686	1901	1,262,439	126,244
1896	816,122	81,612	1902	1,351,703	135,170
1897	905,386	90,539	1903	1,440,967	144,097
1898	994,649	99,465	1904	1,530,230	153,023
1899	1,083,913	108,391			

It is scarcely to be supposed, as Mr. Fleming points out, that the line will be in working order before 1896, and according to this estimate the business done in 1897 would be £90,539; that is to say, in the first year following the establishment of the line the business done might be expected to cover the whole of the working expenses, and to give £30,539 for the renewal fund. After only seven years of working the business done would amount to £144,097, the scheme would be self-supporting, and the contributing Governments would be relieved from any further financial charge. Long before the expiry of the 25 years for which it has been usual to ask for a subsidy the possession of the cable would have become a source of public revenue.

It appears from a further statement included in Mr. Sandford Fleming's memorandum that five of the Australian colonies have in the past two years paid in the form of subsidy and guarantee to the Eastern Extension Company something more than the £52,000 which it is proposed to secure under a joint colonial guarantee in the scheme for a Pacific cable. It is hardly conceivable that, if such a cable were constructed, the Imperial Government would stand aside from contributing its reasonable share. The total amount of the guarantee to be borne by each Government concerned would therefore be relatively small, and as far as Mr. Sandford Fleming's estimates are to be trusted, there is nothing extravagantly impossible in the figures. It is understood that a conference will shortly be held in Canada for the purpose of discussing the scheme more fully, and if it be found to bear the examination of experts, steps will be taken to procure the assent of all the colonial Governments concerned.—*The Times.*

PHYSICAL SOCIETY.

At a recent meeting of the Physical Society (Prof. A. W. Rücker, M.A., F.R.S., president, in the chair), Messrs. J. H. Gillett and F. Hovenden were elected members of the society.

The **President** announced that Mr. Preece's note on the "**Specific Resistance of Sea-Water**" had been temporarily withdrawn.

Prof. G. M. Minchin, M.A., made a communication on the "**Calculation of the Coefficient of Self-Induction of a Circular Current of Given Aperture and Cross-Section.**" Instead of assuming the cross-section of the wire small and the current density constant over the section, as is usually done, the author takes into account the dimensions of the section and the non-uniform distribution of the current. Making use of the expressions for the vector potential, G, of the current given in his previous papers (*Philosophical Magazine*, April and August, 1893), the author calculates the total normal flux of force through a surface intersected once in the positive direction by every tube of force emanating from the given current. This flux divided by the current gives the coefficient of self-induction. The surface chosen is the circular aperture of the current and half of the anchor ring formed by the wire. When the current density is inversely proportional to the distance from the axis of the circular current, the value for the coefficient of self-induction is found to be

$$\pi\left\{4a(L-2)+2c\left(L-\frac{5}{4}\right)-\frac{c^2}{16a}(2L+19)\right\},$$

where a is the radius of the central filament of the current, c the radius of the cross-section of the wire, and $L = \log_e \frac{8a}{c}$. Clerk-Maxwell's approximate expression agrees with this in the principal term. As an example of the closeness of the approximation, the case of a current in a wire two millimetres diameter bent to a circle of two centimetres mean diameter had been taken, the approximate and corrected coefficients being 58·868 and 59·206 absolute units respectively. When the current in the wire is superficial, as in the case of alternating currents of high frequency, the coefficient is somewhat greater, being given by the expression

$$\pi\left\{4a(L-2)+2c\left(L+\frac{3}{2}\right)+\frac{c^2}{16a}(4L+11)\right\}.$$

Incidentally it was pointed out that the function, Gx, where G is the vector potential at a point distance, x, from the axis of a circular current, was the same as Stokes's current function in hydrodynamics.

Another paper on the "**Magnetic Field of a Current Running in a Cylindrical Coil,**" was read by **Prof. Minchin.** The cylindrical coil is regarded as a series of equal circles lying close together and forming a cylindrical surface. Replacing each circular current by its equivalent magnetic shell, the problem of finding the magnetic potential at a point resolves itself into calculating the gravitational potential due to two circular plates of attracting matter, one positive and the other negative, situated respectively at opposite ends of the cylinder. The magnetic potential due to one plate is then deduced in terms of elliptic integrals of the first, second, and third kinds. The president had pointed out that the expressions given in the printed proof of the paper only applied when the perpendicular from the point to the plate fall within the circle. The author had, therefore, modified the formula so as to be true generally. From this formula the equipotential curves can be constructed. The same system of curves serve for the plate at the other end of the cylinder by changing the signs of the numerals representing the potentials and giving the curves a motion of translation equal to the length of the cylinder in the direction of its axis. The equipotential curves for the coil can then be deduced by drawing through the points of intersection of the two sets of curves whose numerical values have a constant sum. In determining the curves the author had to calculate tables of elliptic integrals of the third kind, and these he hoped to complete

before the paper was published. In reply to a question on the first paper which had been brought before him by Prof. Perry, the author said that as the diameter of the wire diminished indefinitely, both the self induction and resistance became infinite, but the ratio, L/R, became zero. It was interesting to examine what relation between the aperture and cross section gave minimum impedance. If the ordinary expression for L be taken the problem was impossible, but the corrected form admitted of a solution. **Prof. Perry** hoped the work Prof. Minchin had done so well for circles and cylinders would be extended to cylindrical coils of rectangular cross section. It was most important to be able to find the shape of the field produced by such coils. **Prof. S. P. Thompson** enquired if there was any way of deducing the expression for the magnetic force at a point other than that given in the paper on the "Magnetic Field of a Circular Current" (*Philosophical Magazine*, April, 1893). In reply, **Prof. Minchin** explained how the formula followed at once from the fundamental theorem that magnetic force is the curl of the vector potential. This was based on Laplace's expression for the force between a magnetic pole and an element of current, which had been proved experimentally.

A paper, by **Mr. J. Swinburne**, was then read on "**A Potentiometer for Alternating Currents.**" This was given in our last issue.

BUSINESS NOTES.

Hyde Park.—The St. George's Vestry intend to introduce the electric light in the conveniences at Marble Arch.

Penrith.—The Penrith Board of Health have agreed not to proceed for 12 months with the proposed application for electric lighting powers.

Tunbridge Wells.—Mr. W. H. Preece is preparing plans and specifications for the new buildings, machinery, and central station for the Town Council.

Wolverhampton.—The Corporation invite tenders by January 2 for a complete travelling crane, and by January 1 for the erection of an electric light station.

Renfrewshire.—The contract for lighting Houston House, Renfrewshire, for Lady Anne Speirs, has just been given to Messrs. Tayler, Smith, and Co.

Change of Address.—Major General Webber, C.B., consulting electrical engineer, has removed his office from Portland House, Basinghall street, E.C., to 27, Chancery lane, W.C.

Port Talbot.—A proposal to form a sub committee to consider the question of the lighting of the district of the Margam Local Board will be moved at the next meeting of the latter.

Breach of the Factory Act.—The West Hartlepool Steel and Iron Ore Company were on Wednesday fined £5 and costs for a breach of the Factory Act, in not having the engine driving the electric plant protected.

Aluminium Company.—The petition by the Aluminium Company for the reduction of its capital from £400,000 to £80,000, by reason of loss of capital, has been renewed. Mr. Justice Wright has granted leave to amend the petition.

Huddersfield.—Mr. Calvert, in moving the adoption of the minutes of the Electric Lighting Committee of the Town Council, mentioned last week that in a few days they would be able to double the supply of current for public lighting.

Blackpool.—Mr. T. Parker has made an examination of the Blackpool tramway, and will report on its condition to the Corporation. An installation of the electric light is in progress at Messrs. Garlick and Sykes's office, the first of its kind in the town. Messrs. Challoner are carrying out the work.

City and South London Railway.—The receipts of the Company for the week ending December 24 were £950, against £926 for the same period last year, or an increase of £24. The total receipts for the second half year of 1893 show an increase of £167 over those for the corresponding period of 1892.

Chiswick.—At the last meeting of the Local Board the clerk read a document from the Board of Trade, together with a copy of the proposed regulations for the electric lighting of Chiswick. The letter was referred to the Works Committee, the surveyor being instructed to look into the matter and report.

Newport.—A deputation from the County Council have paid a visit to Bristol and inspected the electric light station on the Welsh Back and the installation as far as it has progressed, in the city of churches. The committee got a good notion of how to deal with narrow streets such as are in evidence in Newport.

Nottingham.—Mr. W. J. Furse, who for the past 12 years has held the position of engineer and manager for Mr. Joseph Blackburn, has resigned his position, and bought the business of the late Mr. Josiah Till, Burton street, Nottingham, manufacturer of lightning conductors, etc., and will continue the business on his own account at that address.

Acme and Immisch Electric Works, Limited.—This Company has been registered with a capital of £25,000 in £1 shares. The object is to amalgamate the undertaking of the Acme Works, Chalk Farm, N.W., and the General Electric Power and Traction Company, Limited, of Kentish Town, N.W., and to carry on business as electrical and mechanical engineers, etc.

Dundee.—At a meeting of the Dundee Police Commission, Mr. Ballingall called attention to a minute regarding the lighting of the central police buildings by electricity. He said that they had not yet received a comparative statement as to the cost of the electric light and the cost of gas. The approval of the minute was moved by Treasurer Willsher, and the minute was adopted.

Richmond.—The Richmond (Surrey) Town Council have referred back to the Electric Lighting Committee a proposal that the electric light should be adopted for illuminating certain streets in the town, and that a contract should be made with the Richmond Electric Light Company. The latter has been formed, with a capital of £50,000, to take over the powers of Messrs. Latimer Clark, Muirhead, and Co., Limited.

Swansea.—Tenders are invited by January 4th by the Swansea Harbour Trustees for the working, maintenance, and renewal of the electric light machinery and plant for five years (subject to earlier determination by the trustees). Particulars and forms of tender may be obtained on application to the trustees' engineer, Mr. A. J. Schenk. Tenders, sealed and addressed to Mr. Talfourd Strick, clerk, Harbour Offices, Swansea, and marked on the outside "Tender—Electric Lighting," should be delivered at the Harbour Offices, Swansea, by the date mentioned.

Messrs. Robey and Co.—We are informed that Messrs. Robey and Co., engineers, of the Globe Works, Lincoln, have converted their business into a limited liability company, with an authorised share capital of £300,000 in preference and ordinary shares, £272,710 of which are taken by the partners and holders of capital in the old firm, no issue of any of the Company's share capital having been offered to the public. In addition to the above capital of £300,000, there will be an issue of £125,000 4½ per cent. debentures—making a total capital of £425,000. This change has been made in consequence of the deaths of partners, and to facilitate family arrangements, leaving the present management of the business unaltered.

Llandudno.—The Town Improvement Commissioners have received a letter from Messrs. R. Bellis and W. Kingsland, submitting a scheme for the introduction of the electric light into Llandudno. They were prepared, with the sanction of the Commissioners, to take immediate steps to form a company of local gentlemen and apply to the Board of Trade for a provisional order. It was decided to consider the subject at a special meeting to be held in January, the clerk in the meantime to report what effect such companies have had on other towns; also to write to Messrs. Bellis and Kingsland, enquiring on what terms, if the Board favoured the proposal, they would be prepared to transfer their undertaking when it had been fully established.

Lighting at Prescot.—It is alleged that the electric lighting of the town is defective. A special meeting of the Local Board was held last week to receive a report from the surveyor and assistant surveyor as to the public lighting. The surveyor (Mr. Goldsworth) read a report on the subject, and a letter was received from the managing director of the British Insulated Wire Company, Prescot, who have the contract for the lighting, saying that the defects in the lighting would be remedied without delay. A resolution was passed appointing Mr. Dyson and the surveyor to wait upon the managing director of the Wire Company to point out the serious inconvenience arising from a certain number of lamps not being lighted, and to ascertain how soon the defective lighting would be remedied.

Coventry.—The Town Council have adopted the report of the Electric Light Committee. The committee reported that Mr. R. Hammond had attended the committee meeting and submitted specification and general conditions for the installation of the generating and distributing plant, and the same were considered and settled by the committee, the amount of the contract being £9,185, the trenching of the streets to be left in the hands of the Corporation. It was ordered that the amount of security to be given by the contractors be £2,000. At the same meeting a letter from Messrs. Fowler, Limited, Leeds, was read. The letter stated that Mr. Hammond was not now, and never had been, a shareholder in the company, and he had not, and never had had, any pecuniary interest in it.

Personal.—A marriage has recently taken place between Mr. Ernest George Tidd, A.M.I.C.E., A.I.E.E., of Glasgow, and Miss Helen Kate (Nellie) Bond. Mr. Tidd has for the last five years been on the staff of Messrs. Paterson and Cooper, and as engineer of their contract department has superintended some of the large installations recently erected by them. He has lately left London for Scotland as manager of Messrs. Paterson and Cooper's ship-lighting and Scotch branches at 137, West Regent street, and Maritime buildings, Dundee. Mr. Tidd was presented with a handsome hall gong by Messrs. Paterson and Cooper's London outdoor employés.—We understand that Mr. H. G. Massingham is no longer on the board of directors of the City of Bath Electric Lighting and Engineering Company, Limited, and that Mr. J. Bigland Wood is a new director.

Lighting of Fleetwood.—A special meeting of the Improvement Commissioners has been held to consider the chairman's report with reference to the electric lighting scheme, and to which reference was made in our last issue. The Chairman considered that every praise was due to the committee. He firmly believed the committee had arrived at the best conclusion possible. Mr. Davies endorsed these remarks. Mr. Davies moved, and Mr. Leadbetter seconded, that the Brush Company's tender for the necessary plant at about £9,000 should be accepted, subject to the consent of a public meeting of ratepayers, the Board of Trade, the Local Government Board, and the Postmaster General. The resolution was carried unanimously, and it was decided to give the requisite instructions for the preparation of plans, etc., required for the electric lighting station and gas tank in the town's yard, London street, together with the construction of transformer-chambers in streets, the committee being empowered to invite

applications for the appointment of a resident working electrical engineer. The Clerk said a town's meeting would probably be held early in January.

Bournemouth.—The Town Council have adopted the report of the Lighting Committee, who stated that they had received a deputation, consisting of Messrs. Leveson Scarth and J. A. Hosker, on behalf of the Bournemouth and District Electric Supply Company, the deputation pointing out to the committee the amendments suggested by the company in the draft license, and stating that those suggestions should be communicated to the town clerk in writing. This having since been done, the committee recommended the Council to agree to certain literal alterations in the wording of the license. The report, as mentioned, was adopted. Replying to Councillor Jenkins, as to whether the electric light company had a monopoly in Bournemouth, the Town Clerk explained that they had a monopoly to the extent that no private individual or company were able to generate and supply electric light without a provisional order or license, and that such was not likely to be granted if the present company carried out their work satisfactorily. The Corporation, however, in their license took powers to provide public lighting for their own purposes, and had power to purchase the works of the company on certain conditions.

Result of Sunderland Tenders.—The Highways Committee of the Corporation has had under consideration the tenders for supplying the plant for the introduction of the electric light. The following have been accepted: Boilers and mountings, Messrs. Hawksley, Wyld, and Co., Sheffield, £1,380; engine and dynamos, Messrs. J. H. Holmes and Co., Newcastle, £4,340; alternators, Crompton and Co., Chelmsford, £1,352; batteries, Electrical Power Storage Company, £763; insulated cables, India Rubber Works, Silvertown, £2,592; road work, Mr. G. Simpson, Newcastle, £2,590; ironwork, Messrs. McLaren, Glasgow, £296; stonework, Messrs. Wilks and Maplebeck, Birmingham, £236. The total amount of the tenders is £15,074, against a sum of £21,000 estimated. On Wednesday, the Highways Committee, at the fortnightly meeting of the Sunderland Council, recommended the acceptance of the eight tenders for carrying out the work necessary for the introduction of electric lighting, and that the Finance Committee be directed to borrow £25,000 in connection with the same. Alderman Bell moved, and Alderman Wilson seconded, the adoption of the report, which, after some discussion, was adopted.

Woodhouse and Rawson, Limited.—A meeting of the creditors and debenture holders in Woodhouse and Rawson United, Limited, was held last week to consider the scheme of reconstruction propounded under the winding-up order. Mr. C. J. Stewart, the official receiver, presided, and stated that, according to the books of the Company, there was £28,000 still unaccounted for. The directors estimated a surplus of £29,636, but three of the directors—Sir Wm. Rawson, Mr. Samuel Pope, Q.C., and Mr. A. L. Foley—said they did not hold themselves personally responsible for that statement. He understood that it was extremely doubtful whether the debenture holders would receive 20s. in the £. They must, he said, look with extreme doubt on the statements as to the reconstructed Epstein Electric Company, and his estimate was that there would be nothing for the unsecured creditors and that there would be a deficiency of £43,000. Examining the accounts, he pointed out that the gross income in the year ending June 30, 1890, was put down at £109,597, the items including £37,235 in respect of the promotion of the International Okonite Company, Limited, of which company Mr. Samuel Pope became a director, and which had paid one dividend in its first year. He concluded that of the total income in that year only £21,491 could be properly put down to the credit of an industrial enterprise. The expenditure in the same year was £48,512, the loss in 1891 was £43,000, and in 1892 £129,000. Practically, the business that had been the means of giving 15 per cent. to the shareholders for two years had been the promotion of other companies including the Okonite, the Elmore, and Phœnix Companies. The last mentioned company was formed entirely for financial purposes. The business now was whether it was desirable to appoint a liquidator and a committee of inspection. Mr. Pope, Q.C., said he had stuck to the concern both in person and in pocket so long as there was any concern to stick to. He was a director and a large shareholder, and he would lose probably as much as anyone in the room. He would prefer that they should leave the matter in the hands of the official receiver until electric traction was fully developed, and then the creditors would get the benefit of it. Mr. Stewart was appointed the official liquidator, and, after a somewhat warm discussion, a committee of creditors was appointed to act with the committee of contributories in assisting the official liquidator.

Lighting of Chelmsford.—The Town Council again sat in committee last week to consider the provisional order for which Messrs. Crompton and Co., Limited, are applying to the Board of Trade in connection with the electric lighting of Chelmsford. The order would empower Messrs. Crompton to supply electric lighting in Chelmsford for 42 years and to charge for every amount up to 20 units 13s. 4d., each unit over to be charged 8d. The committee saw no objection to this order, provided the price charged to consumers was reduced from 8d. to 6½d. for every unit over 20 units, and provided the company gave an undertaking that they would allow a discount of ½d on every unit over 20 units if the money was paid within a month, and provided a clause was inserted giving the Council the option of purchasing the undertaking at the end of 21 years or 31 years by valuation. Alderman Morton elicited from the town clerk that if this provisional order was granted it would not hinder the local authority under the Act of Parliament from undertaking the public lighting of the town at the expiration of the contract with Messrs. Crompton. Mr. Gray denied that the Council by agreeing to the order would be granting Messrs. Crompton a monopoly, while he reminded the meeting that the Arc Works was an important industry to the town, and the Council should grant every facility to the company that was consistent with the interests of the burgesses. This view was shared by other councillors, Mr Taylor reminding the Council that in this matter they were amply protected by the Board of Trade. Alderman Chancellor moved as an amendment that the period of the provisional order should be reduced to 20 years, but this found no support. Mr. F. Whitmore then moved an amendment recommending the Council to support the order, with the exception of Clause 80 (which deals with the question of purchase). Mr. Gray seconded, and Mr. Maskell withdrawing his motion in favour of it, it was ultimately put to the meeting and carried with only one dissentient. Clause 80 was next discussed. Alderman Chancellor was of opinion that their purchasing powers should be clearly defined, and a clause was finally accepted to the effect that, in the event of a sale, the company should sell to the local authorities all buildings, lands, and plant used for the public lighting of the town. It was also resolved to include a clause giving the Council power to purchase at the expiration of 21 or 31 years, the terms of purchase to be in accordance with conditions specified in Section 2 of the Electric Lighting Act, 1888, and that the Council should only purchase such materials, buildings, plant, etc., as might be necessary for the public and private lighting of the town.

Refuse as Fuel.—In our last issue we referred to a scheme which the Harrogate Corporation has decided to adopt for the drying, sorting, and combustion of refuse, and for its application as a steam generator for the lighting of the town by electricity. In view of the latest development which this question has reached, a representative of a provincial paper paid a visit a day or two ago to the works established at King Cross, Halifax, for testing another appliance—the Livet system of generating steam by the destruction and combustion of town refuse. The correspondent describes the system as follows: The system differs somewhat from that at Harrogate. It involves no drying or sorting, the refuse being put into the furnace just as it comes from the dusthole or rubbish heap, without any preparation whatever. The material is simply a substitute for coal; indeed, not a particle of coal is used, and it is claimed that three tons of the refuse is equal to one ton of the best coal. The boiler is so constructed that it has about double the heating surface of the largest type of Lancashire boiler. Round this boiler flues are arranged in such a manner as to create an enormous natural draught, which enables all classes of fuel to be burnt very economically. In the case of dusthole rubbish and town refuse generally 3lb. to 4lb. of water can be evaporated to every pound of the refuse, and this, it is claimed, without creating either smoke or smell, as the excessive draught in the furnaces causes such perfect combustion, and raises the temperature of the gases to such an enormous heat, that the whole of the impurities are entirely destroyed. The consumption of rubbish per foot of grate surface super is very large, and enables a great amount of the material to be got rid of. At the same time, assuming that the whole of a town's refuse is utilised in this way, it is contended that the evaporation will produce enough steam power to light the whole of the town by electricity. The object at which this apparatus aims, in addition to the destruction of the refuse, is the generation of steam. Of course, the steam can be adopted for any purpose, but the most obvious use to which a corporation would put it would be that of driving electric lighting dynamos. It is said that three boilers like the one erected at Halifax would enable the whole of that town and its suburbs to be illuminated with the electric light. In order to demonstrate the efficiency of the system a powerful steam dynamo has been fixed in connection with the boiler, and the works lighted by means of a number of incandescent and arc lamps. But the most brilliant effects are produced by means of a dazzling searchlight of 25,000 c.p. The illumination now produced is said to represent but a tithe of the capabilities of even the one boiler now in use. The works have only just been completed, and an opportunity will soon be afforded to representatives of the corporations, steam users, and other interested in the question to see the apparatus in operation.
